## Chapter 1: MGA Product Overview

1.1 Introduction .....	1-2
1.1.1 MGA Chipset.....	1-2
1.1.2 Features .....	1-3
1.1.3 Driver Support .....	1-3
1.1.4 Windows Support.....	1-3
1.1.5 Video Support.....	1-4
1.1.6 Software Developer Support.....	1-4
1.1.7 Documentation .....	1-4

## Chapter 2: ATHENA Overview

2.1 Introduction .....	2-2
2.1.1 Bus Interface.....	2-2
2.1.2 VGA .....	2-2
2.1.3 Bus Interface FIFO (BFIFO).....	2-2
2.1.4 Address Processing Unit (APU).....	2-4
2.1.5 Data Processing Unit (DPU).....	2-4
2.1.6 ZIALU .....	2-4
2.2 Frame Buffer .....	2-4

## Chapter 3: Operation Modes

3.1 VGA Mode .....	3-2
3.1.1 FlexFont.....	3-2
3.1.2 Enhanced Modes .....	3-2
3.1.3 Display Adapter Support .....	3-3
3.1.4 Differences Between ATHENA Ports and IBM VGA Display Adapter Ports .....	3-3
3.1.4.1 Hercules Mode Port Differences .....	3-3
3.1.4.2 CGA Mode Port Differences.....	3-3
3.1.4.3 EGA Mode Port Differences .....	3-3
3.1.4.4 VGA Mode Port Differences .....	3-3
3.2 Power Graphic Mode.....	3-4
3.2.1 Memory Configurations .....	3-4
3.2.2 Pixel Format.....	3-9
3.2.3 Overview of Drawing Operations .....	3-12

3.2.4	DMA and Pseudo DMA .....	3-13
3.2.4.1	DMA .....	3-17
3.2.4.2	Pseudo DMA .....	3-19
3.2.5	Programming the CRTIC for Power Graphic Mode.....	3-21
3.2.5.1	Registers.. .....	3-21
3.2.5.2	Interlace Modes .....	3-21
3.2.5.3	Hardware Panning .....	3-21
3.2.5.4	Hardware Zooming .....	3-21
3.2.5.5	Programming Constraints .....	3-22
3.2.5.6	Frame Buffer Alignment .....	3-23
3.2.5.7	Overscan .....	3-24
3.2.6	Interrupts .....	3-24
3.3	Access Restrictions to Some Resources .....	3-25
3.4	Initialization and Configuration .....	3-26
3.4.1	Configuration Elements .....	3-26
3.4.2	Booting in VGA Mode .....	3-26
3.4.3	Booting in Power Graphic Mode.. .....	3-27
3.5	Mode Switching .....	3-27
3.5.1	Switching From VGA Mode to Power Graphic Mode.....	3-27
3.5.2	Switching From Power Graphic Mode to VGA Mode.....	3-28
3.6	Power up and Reset.. .....	3-29
3.6.1	Hard Reset .....	3-29
3.6.2	Soft Reset.. .....	3-29
3.6.3	Configuring ATHENA in a Board-level Design.....	3-30
3.6.3.1	Special Considerations for PCI. ....	3-32
3.6.4	Reset Field Definitions .....	3-32

## Chapter 4: Memory Mapping

4.1	ISA and PCI Configurations .....	4-2
4.1.1	Configuration Space Mapping.....	4-2
4.2	Memory Space Mapping.. .....	4-2
4.2.1	ISA Interface .....	4-2
4.2.2	PCI Interface.. .....	4-3
4.2.3	Power Graphic Mode Mapping (ISA and PCI) .....	4-3
4.3	I/O Mapping .....	4-8

## Chapter 5: Register Descriptions

5.1 Register Descriptions .....	5-2
5.1.1 Power Graphics Mode Registers .....	5-2
5.1.2 VGA Mode Registers .....	5-3
5.2 Power Graphic Mode Register Descriptions .....	5-4
5.3 VGA Mode Register Descriptions .....	5-63

## Chapter 6: Hardware Interface

6.1 Introduction .....	6-2
6.2 Host Interface .....	6-2
6.2.1 PCI Interface .....	6-2
6.2.1.1 PCI Bus Operation .....	6-2
6.2.1.2 PCI Cycles .....	6-5
6.2.1.3 Bus Sizing .....	6-6
6.2.1.4 External Devices .....	6-6
6.2.2 ISA Interface .....	6-7
6.2.2.1 Bus Sizing .....	6-7
6.2.2.2 External Devices .....	6-9
6.3 VRAM Interface .....	6-10
6.3.1 Memory Interleave .....	6-12
6.3.2 Patch RAM .....	6-13
6.3.3 ZTAG RAM .....	6-13
6.3.4 MCTLWTST Register Timings .....	6-13
6.3.5 VRAM Interconnect .....	6-17
6.3.6 Coprocessor Requests .....	6-21
6.4 VIDEO Interface .....	6-22
6.4.1 Power Graphic Mode (No DUBIC Mode) .....	6-22
6.4.2 Power Graphic Mode (DUBIC Mode) .....	6-24
6.4.3 VGA Mode .....	6-25
6.4.4 Slaving ATHENA .....	6-25

## **Chapter 1: MGA Product Overview**

***T**his chapter contains an overview of the Matrox MGA chipset features and software products.*

## 1.1 Introduction

Matrox MGA is a high-speed, high-resolution graphics accelerator series of products designed for the power user. MGA is very suitable for GUI environments such as Microsoft Windows 3.1 and Windows NT, IBM OS/2 PM, Unix X-Windows, and AutoCAD. It offers ultra high resolution displays with true color, real-time 3D, and many other innovative hardware and software enhancements.

MGA's 64-bit graphics power, in combination with a 486 or Pentium-class PC is in our opinion the best graphics solution if you require true workstation-level performance at a reasonable price.

### 1.1.1 MGA Chipset

The Matrox ATHENA chip lies at the heart of MGA's powerful graphics capabilities. It offers an ISA interface for ISA bus products, and a PCI interface for PCI systems. Several possible memory configurations permit design of 8,16, 24, and 32 bits/pixel displays at resolutions up to 1600 x 1200 pixels. Figure 1-1 shows a block diagram of a typical graphics display adapter which uses the MGA ATHENA chip.

**Figure 1-1: Typical Implementation Block Diagram**

The chipset functions as a stand-alone graphics controller that features an integrated VGA to offer both VGA Mode and high-resolution Power Graphic mode operation. It contains a 32-location Command FIFO and address and data processing units (APU, DPU). In addition, LINE, Trapezoid, and BITBLT drawing operations are available, supported by DMA and Pseudo DMA transfers. These enhancements make screen operations such as redrawing and scrolling appear instantaneous.

ATHENA is pin-compatible with the MGA ATLAS chip, so ATLAS-based designs can take advantage of ATHENA's additional features without modification to the board's design.

## 1.1.2 Features

- From 1 to 6 MB of frame buffer VRAM in configurations up to 32 bits/pixel
- . VRAM block write operations for maximum speed
- Photo-realistic true color display, and QCDP (Quality Color Dithering Process) for displays of less than 24 bits/pixel
- . Ultra-high resolution of 1600 x 1200, with 256 colors
- . Workstation performance with speeds from 2 to 12 times faster than competitors' boards
- . 64-bit frame buffer data bus width
- . Available Z-buffer option (2 to 4 MB DRAM)
- . Hardware assisted Gouraud shading and depth-cued wireframe
- . Integrated VGA, for full support of all DOS applications, eliminating the need for a separate VGA card
- . Integrated 3D graphics engine
- . Integrated PCI interface
- . Direct RAMDAC interface
- . Fast, flicker-free refresh rates up to 120 Hz
- . Support for ISA, VESA VL, Micro Channel, EISA, PCI, and other architectures
- . Installation of up to four boards in a system

## 1.1.3 Driver Support

MGA Power Drivers are available for Windows 3.1 and AutoCAD Rel. 11/12. The 'MGA Supplementary Drivers' package contains drivers for Windows NT, OS/2, and MicroStation (with dual display).

We provide:

- . Support for popular Windows and DOS design and presentation applications
- DynaView driver for AutoCAD Release 11 and 12 that includes real-time scroll bars, spy glass, and bird's eye view, etc.
- Support for AutoCAD 12 for Windows, and MicroStation PC
- . A 3D library which supports SXCI, with planned support for OPEN GL and HOOPS

## 1.1.4 Windows Support

- . Control Panel for Windows controls the PixelTouch hardware pan and zoom, Virtual Desktop, and 'on the fly' resolution switching (without rebooting Windows) through the use of hotkeys.
- Font anti-aliasing in hardware
- . In addition to the drivers listed above, the 'MGA Supplementary Drivers' package also contains the ConsistentColor monitor calibration utility to ensure accuracy between your screen display and the printed output, and the WinSqueeze! on-the-fly JPEG file compression utility, which can achieve compression ratios of up to 28:1.

### 1.1.5 Video Support

- **MGA** interfaces with the Matrox Marvel video capture/video windowing board.
- The MGA VideoPro NTSC/PAL encoder provides output capability for recording presentations, animations, and AutoCAD walk-throughs to tape.
- Hardware-assisted Video for Windows (VfW) and Indeo are supported.

### 1.1.6 Software Developer Support

- . Software libraries (SXCI) are available for developers for the DOS and Windows 3.1 platforms, with support planned for HOOPS and Open GL. SXCI is a complete 2D/3D API which fully exploits MGA's hardware acceleration capabilities.

### 1.1.7 Documentation

Other documentation available for Matrox MGA products includes:

- *MGA TITAN Specification (103 1&MS)\** A description of the Matrox MGA TITAN chip.
- . *MGA ATLAS Specification (10348-MS)\** A description of the Matrox MGA ATLAS chip.
- . *MGA DUBIC Specification (10232-MS)\** A description of the Matrox MGA DUBIC chip.
- . *MGA SDK Manual (10330-MF)* A user/reference manual for the MGA software developer's kit for DOS and Windows 3.1.
- . *MGA DynaView /2D for AutoCAD Manual (10345MN)* A user/reference manual for the Matrox MGA DynaView driver for AutoCAD and 3D Studio.
- *MGA Supplemantary Drivers Manual (10352-MN)* An installation/user manual which describes our OS/2, Windows NT, and MicroStation PC drivers, as well as the MGA WinSqueeze! and ConsistentColor programs for the Windows platform.

\* Like the *ATHENA Specification*, these are restricted documents. See your Matrox Sales representative for more details.

The *PCI Bus Specification* from the PCI Special Interest Group contains additional information on hardware implementation for the PCI architecture.

---

## ***Chapter 2: ATHENA Overview***

***T***his chapter introduces the Matrox MGA ATHENA chip and its component sections.

## 2.1 Introduction

The Matrox ATHENA chip supports both VGA and Power Graphic mode displays. VGA mode supports the VGA standard, while Power Graphic mode provides additional high-speed, ultra-high resolution displays. You can switch between the two modes while using the same monitor for both. ATHENA can be configured for PCI bus systems, or for ISA (and other) bus systems.

The ATHENA chip is a stand-alone graphics controller which is composed of several sections that work together to accomplish the many tasks required of them. The ATHENA sections are listed below, and discussed in the following sections of this chapter.

- Bus Interface
  - . VGA
  - . Bus Interface FIFO (BFIFO)
  - . Address Processing Unit (APU)
- Data Processing Unit (DPU)
- ZIALU

### 2.1.1 Bus Interface

This section of ATHENA implements the interface with the host. Two bus interfaces are supported: an ISA interface and a PCI interface for the PCI bus.

The Bus Interface section includes:

- All of the control circuitry for the ISA and PCI buses
- PCI control, decoding, and re-mapping circuitry
- Configuration registers
- I/O buffers @-location FIFO for **writable** devices; 4-location FIFO for **ILOAD** operations)
- Byte-alignment circuitry; 32-to-8 bit access conversion for VGA and I/O
- The data path (data and addresses) from the host

### 2.1.2 VGA

This section implements the VGA functions, and includes:

- The VGA core, which interfaces directly with the frame buffer in VGA mode
- The circuitry for video refresh in Power Graphic mode (see Section 6.3.6), which includes address generation, data transfer requests, and video control circuitry

### 2.1.3 Bus Interface FIFO (BFIFO)

- This section implements the Command FIFO from the host to the drawing engine. All access to the drawing registers passes through this 32-location FIFO, which holds the data as well as the address of the targeted register in the drawing engine.

Figure 2-1: ATHENA Block Diagram

## 2.1.4 Address Processing Unit (APU)

This section of ATHENA generates the sequencing of the drawing operations. Each drawing operation is broken down into a sequence of read and write commands which are sent to the DPU. The APU includes:

- Generation of the sequence for each drawing operation, and the addresses and mask
- Processing of the slope for vectors and trapezoid edges
- Rectangle clipping

## 2.1.5 Data Processing Unit (DPU)

This section manipulates the data according to the currently-selected operation. It also converts read and write commands from the APU into memory cycles to the frame buffer. The DPU includes:

- Generation of memory cycles
- Host compress, decompress, and data formatting
- The funnel shifter for data alignment
- The Boolean ALU
- Anti-aliasing
- The patterning and dithering circuitry
- The Data FIFO for **BitBLIT** operations
- The color expansion circuitry for character drawing
- The depth comparator

## 2.1.6 ZI ALU

This section implements the ALU for linear interpolation for Z and for Gouraud shading (R,G,B).

## 2.2 Frame Buffer

ATHENA can interface directly with the VRAM and DRAM. Memory combinations of 128K×8 VRAM, 256K×8 VRAM, 256K×16 VRAM, and 256K×16 DRAM are supported in order to permit design of different display configurations. This allows ATHENA to support 8, 16, 24 and 32 bits/pixel formats and resolutions up to 1600x1200.

VRAM is used for the frame buffer itself. Since VRAM has two ports, the serial port of the VRAM is used for the screen refresh while the random port is devoted to drawing operations. Useful VRAM functions such as split data transfer, block mode, and write/bit are all exploited.

---

## **Chapter 3: Operation Modes**

***T***his chapter explains the VGA and Power Graphic operation modes of the Matrox MGA ATHENA chip. The Power Graphic mode description contains explanations of the memory configuration, frame buffer formats, drawing operations, initialization, configuration, and reset.

## 3.1 VGA Mode

ATHENA's VGA contains all of the functions and support logic required to implement the IBM VGA, EGA, and CGA display adapter and MDA/ Hercules graphics card standards at a register-compatible level.

Since ATHENA is register-compatible with VGA, EGA, CGA and MDA/Hercules adapters, all display modes for these adapters can be supported. As with most display adapters, a BIOS is required to configure ATHENA for each display mode.

As well as the standard control registers required by the various display adapters, ATHENA uses auxiliary registers to enable enhanced modes and emulation functions.

### 3.1 .1 FlexFont

In all alphanumeric modes, FlexFont is an available option. When enabled, it forces the character backgrounds to a single color and allows bits D4-D6 of the attribute byte to be used for character font selection. Up to eight character fonts can be displayed simultaneously. The character fonts are programmable and are stored in Dynamic Memory Plane 2.

### 3.1.2 Enhanced Modes

ATHENA enhances some display modes, and provides new high-resolution 256 and 16-color VGA modes.

The ATHENA chip permits high resolution VGA display modes of 640x400, 640x480, 800x600, or 1024x768 pixels with 256 simultaneous colors, both interlaced and non-interlaced. ATHENA also permits 16 color resolutions of up to 1024x768 interlaced and non-interlaced. Bits in the ATHENA auxiliary registers are used to enable these modes. Otherwise, the programming for these modes is similar to that for VGA modes 13h and 12h.

VGA mode 13h can be enhanced to provide up to 16 pages at 320x200 resolution with 256 colors (standard VGA supports only one page). The CPU can access two pages simultaneously, and the others are selected for access using page select bits in ATHENA's auxiliary ports. The CRTC start address register is used to select a page to display, or to scroll through all pages.

### **3.1.3 Display Adapter Support**

Four modes of ATHENA VGA operation and emulation are available: VGA, EGA, CGA, and MDA/Hercules.

The VGA and EGA CRTC's are fully implemented and are used to perform the operations of a 6845 CRTC for the CGA and MDA/Hercules modes.

The control registers of the CGA and MDA/Hercules adapters are fully supported in the ATHENA hardware. When a control register bit is changed, a trap interrupt (NMI) is generated. The interrupt handler then interprets the control register's contents and sets up the VGA CRTC to perform the required operation. In addition, the chip can be configured to allow software emulation to override any or all of the hardware functions to permit support of special display modes.

### **3.1.4 Differences Between ATHENA Ports and IBM VGA Display Adapter Ports**

There are differences between ATHENA's VGA mode and the IBM display adapters that it emulates. Some ports are changed from write-only to read/write to simplify emulation. Other ports have been deleted because they aren't required. The list below describes the differences.

#### **3.1.4.1 Hercules Mode Port Differences**

The 6845 CRTC is replaced by the EGA or VGA CRTC. Hardware emulation of the 6845 requires software assistance and is enabled through the trap and emulation control registers.

The mode control and configuration registers are now read/write.

#### **3.1.4.2 CGA Mode Port Differences**

The 6845 CRTC is replaced by the EGA or VGA CRTC. Hardware emulation of the 6845 requires software assistance and is enabled through the trap and emulation control registers.

The mode control and color select ports are now read/write.

#### **3.1.4.3 EGA Mode Port Differences**

The CRTC registers are now read/write. Otherwise, the CRTC is identical to the IBM EGA CRTC when the EGA CRTC mode is selected. The VGA CRTC can be selected when ATHENA is in EGA mode.

The attributes controller registers are now read/write. The address and data registers of the sequencer and graphics controller are also read/write.

Graphics position registers A and B have been deleted and replaced by read-only ports for the feature control and miscellaneous registers. Graphics position A is fixed at 0 and B is fixed at 1, according to standard EGA programming practice.

#### **3.1.4.4 VGA Mode Port Differences**

In VGA mode, ATHENA is register compatible with the IBM VGA. The light pen set and clear ports remain accessible. The EGA CRTC can be selected when ATHENA is in VGA mode.

## 3.2 Power Graphic Mode

Power Graphic mode employs hardware-coded graphical acceleration to improve the speed of GUI (Graphical User Interface) environments.

### 3.2.1 Memory Configurations

Several hardware memory configurations are supported in Power Graphic mode. These configurations can further be organized by the fbm (frame buffer mode) field of the OPMODE register. The three basic configurations are:

1. Support of up to 2 MB of VRAM and 2 MB of DRAM using 128K×8 VRAM. This configuration supports 8, 16, and 32 bit/pixel displays.
  2. Support of up to 4 MB of VRAM and 2 MB of DRAM using 128K×8 and 256K×8 VRAM. This configuration supports 8, 16, and 32 bit/pixel displays.
  3. Support of up to 6 MB of VRAM and 4 MB of DRAM. This configuration supports 24 or 32 bit/pixel displays. Use fbm = 01XX, depending on the amount of available memory and whether the frame buffer is configured as 24 or 32 bits.
- :+ Note: In No DUBIC mode (see page 6-17), only Banks 0, 1, 2, and 3 are supported. Therefore, only fbm = 0, 1, 2, and 3 may be used. Note that fbm = 8, 9, and 11 to 15 are undefined.

In all cases, the resolution depends on the amount of available memory. Section 6.3, ‘VRAM Interface’ contains tables that show which fbms can be used with which hardware configurations. The following figures show the memory mapping of the hardware memory configurations.

#### Memory Configuration Tables:

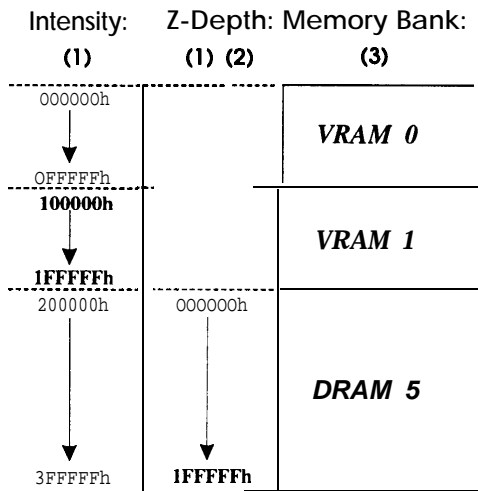

Figure 3-1: fbm = 0

Figure 3-2: fbm = 1

Figure 3-3: fbm = 2

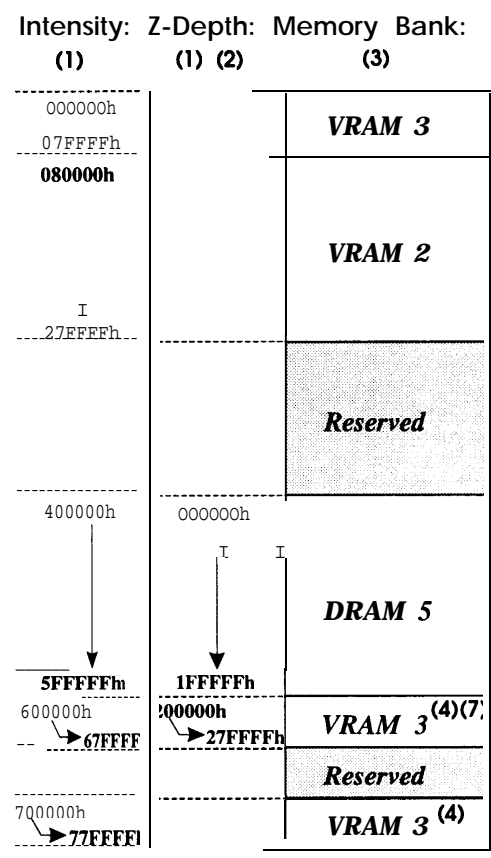

Figure 3-4: fbm = 3

Figure 3-5: fbm = 4

Figure 3-6: fbm = 5

Figure 3-7: fbm = 6

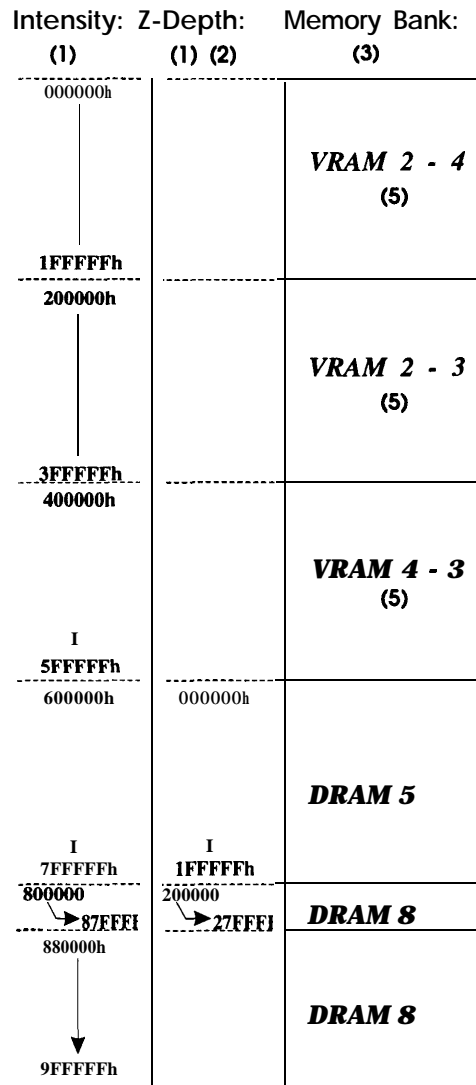

Figure 3-8: fbm = 7

Notes: (Figures 3-1 to 3-9):

- (1) All addresses are hexadecimal byte addresses. These addresses correspond to pixel addresses in 8 bits/pixel mode.
- (2) Depth addresses indicate which memory is used as depth buffer space when 3D drawing is enabled.
- (3) 'Memory Bank' indicates the type of memory used, as well as which bank of memory is used in this space. Refer to Section 6.3 for details on the frame buffer modes.
- (4) This part of the frame buffer can't be used for display.

Figure 3-9: fbm = 10

Notes (continued):

- (5) Depending on the number of chips/banks populated in this section, any data, or possibly only 24-bit data may be stored in this section of memory.
- (6) Depending on the number of chips/banks populated in this section, and if bank 7 is populated, any data, or possibly only 24-bit data may be stored in this section of memory.
- (7) Also visible at 680000h– 6FFFFFFh.

### 3.2.2 Pixel Format

The pixel slice is 64 bits long and is organized as shown below. In all cases, the least significant bit is 0. The Alpha part of the color refers to a section of the pixel which is not used to drive the RAMDAC. In the following illustrations, 'A' refers to Buffer A and 'B' to Buffer B when a double buffer mode is selected. ANTI refers to anti-aliased pixels, and MONO is a monochrome pixel slice.

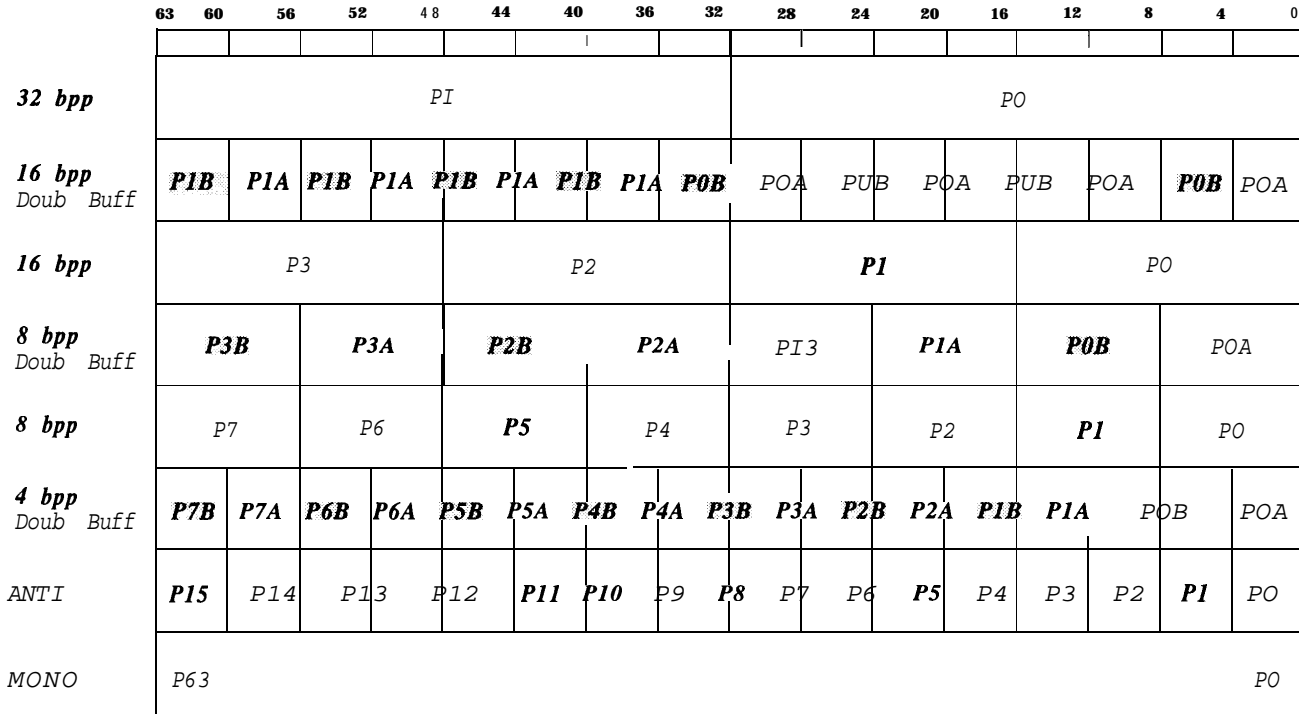

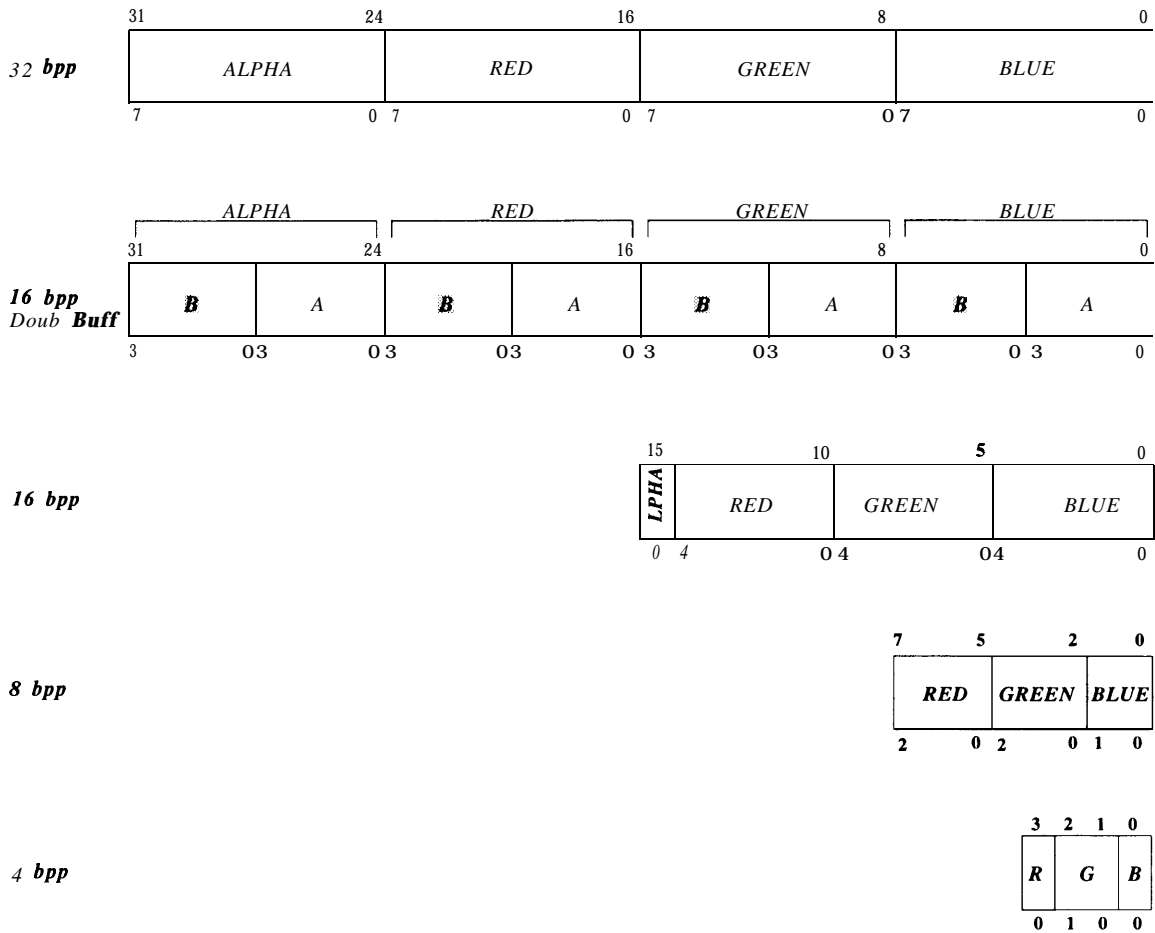

Figure 3-10: Pixel Slice

In all cases the data is true color; however in 8 bits/pixel and 4 bits/pixel formats, pseudo color can be used when shading and anti-aliasing are not used.

The figure on the next page shows how the data is organized for each pixel (for all supported pixel depths).

**Figure 3-11: Pixel Data**

When performing direct frame buffer access, 32-bit access depends on the format of the memory at this location. Data is organized as follows for the various pixel sizes:

**Figure 3-12: 32-bit Access**

In addition to the direct frame buffer access format, the following formats are supported for **ILOAD** and **IDUMP** operations in 1, 24, and 32-bit/pixel modes. These formats are selected by the RGB (hbgr) and compress (hcprs) fields of the Drawing Control (DWGCTL) register:

	32	24	16	8	0	<i>bltmod</i>	<i>hbgr</i>	<i>hcprs</i>			
	<i>As direct frame buffer access</i>					BFCOL	0	0			
	<b>31</b>					BMONO	0	<b>0</b>			
	24	31	16	23	8	15	0	7	BMONO	1	<b>0</b>
	<i>ALPHA</i>	<i>BLUE</i>	<i>GREEN</i>			<i>RED</i>	BUCOL	1	0		
<i>First Word</i>	<i>RED1</i>	<i>BLUE0</i>	<i>GREEN0</i>			<i>REDO</i>	BUCOL	1	1		
<i>Second Word</i>	<i>GREEN2</i>	<i>RED2</i>	<i>BLUE1</i>			<i>GREEN1</i>					
<i>Second Word</i>	<i>BLUE3</i>	<i>GREEN3</i>	<i>RED3</i>			<i>BLUE3</i>					
	<i>ALPHA</i>	<i>BLUE</i>	<i>GREEN</i>			<i>RED</i>	BUCOL	0	0		
<i>First Word</i>	<i>BLUE1</i>	<i>REDO</i>	<i>GREEN0</i>			<i>BLUE0</i>	BUCOL	0	1		
<i>Second Word</i>	<i>GREEN2</i>	<i>BLUE2</i>	<i>RED1</i>			<i>GREEN1</i>					
<i>Third Word</i>	<i>RED3</i>	<i>GREEN3</i>	<i>BLUE3</i>			<i>RED2</i>					

**Figure 3-13: ILOAD/IDUMP Formats / 1, 24, 32 bpp**

### 3.2.3 Overview of Drawing Operations

The following three groups of drawing operations are supported by ATHENA:

- **LINE:** Used for vectors. These operations can be auto-initialized. In this case, the Brezenham parameters are automatically computed by ATHENA. Brezenham parameters can also be provided directly by the host processor.
- **TRAP:** Used for rectangle fills (1 operand BITBLTs) and 3D tile drawing.
- **BITBLT:** Used for copy and other operations (2 operand BITBLTs with or without expansion).

All of these drawing operations support several attributes in order to perform different type of actions. The attributes include: line style, patterning, block mode, raster, antialiasing, Gouraud shading, depth buffer, and others.

The following table summarizes how the drawing engine registers must be initialized for these basic operations:

		REGISTERS																								
		<i>ar0</i>	<i>arl</i>	<i>ar2</i>	<i>ar3</i>	<i>ar4</i>	<i>ar5</i>	<i>ar6</i>	<i>dr0</i>	<i>dr1</i>	<i>dr2</i>	<i>dr3 (Z)</i>	<i>dr4</i>	<i>dr5</i>	<i>dr6</i>	<i>dr7 (Red)</i>	<i>dr8</i>	<i>dr9</i>	<i>dr10</i>	<i>dr11 (Gr.)</i>	<i>dr12</i>	<i>dr13</i>	<i>dr14</i>	<i>dr15 (Blue)</i>	<i>length</i>	<i>SGN</i>
AUTO LINE	INIT END	Xend 2b		Yend 2b-2a			Xstar Xend	Ystar Yend	start X			ZdM ZdM	ZdD ZdD												0	signs
LINE DRAW	INIT END	2b	2b-a-Sdy err	2b-2a 2b-2a					start X			ZdM ZdM	ZdD ZdD												a	signs
TRAP	INIT END	dY1 dY1	eol err1	-ldX1l -ldX1l		e or errr	-ldXrl -ldXrl	dYr dYr	start X			zdx ZdX	ZdY ZdY												lines	signs
BITBLT	INIT END	sea X	ssa X			sca X	syinc syinc																		lines	signs

$$dX = Xend - Xstart$$

$$dY = Yend - Ystart$$

$$a = \max(|dx|, |dy|)$$

$$b = \min(|dx|, |dy|)$$

ZdM = Increment along major axis

ZdD = Increment along diagonal axis

ZdX = Increment along X axis

ZdY = Increment along Y axis

$$eor = dX_r \geq 0 ? -dX_r : dX_r + dY_r - 1$$

$$eol = dX_l \geq 0 ? -dX_l : dX_l + dY_l - 1$$

Where  $x_l$  = left edge;  $x_r$  = right edge

sea = source and address

ssa = source start address

sca = source current address

**Table 3-1: Initialization of Drawing Registers**

Every time a drawing engine operation is started, the following steps must be taken:

1. Since all drawing registers are accessed through the FIFO, check that there is enough room in the FIFO.
2. Initialize all the drawing registers, preferably starting with the 'K' flag registers (see Note (2) following Table 4-5), since some degree of parallelism can be achieved doing this.
3. Start the drawing engine when you write the last register by offsetting the register by 100h.

### 3.2.4 DMA and Pseudo DMA

ATHENA supports two operating modes in which both the address and data are sent via the data bus:

**DMA** A DMA channel on the host system is used to sequence operations.

**Pseudo DMA** The host processor must sequence all access through the DMAWIN memory space (see Chapter 4).

In both cases, the address of the modified register is generated internally by the ATHENA chip. Additional operation modes are available for both DMA and Pseudo DMA:

<b>DMA</b>	<b>Pseudo DMA</b>
DMA General Purpose Write	DMA General Purpose Write
DMA Vector Write	DMA Vector Write
DMA BLIT Write	DMA BLIT Write
	DMA BLIT Read

#### DMA General Purpose Write

The first double word (dw) transferred is loaded into the Address Generator. This dw contains the addresses of the next four drawing registers to be written, and the next four dw transfers contain the data to be written to those four registers.

When each dw of data is transferred, the Address Generator will send the appropriate 7-bit address to the Bus FIFO. When the fourth (final) address has been used, the next double word transfer reloads the Address Generator.

A direct access to a drawing register during a Pseudo DMA General Purpose write resets the Address Generator state machine to the 'LD ADR\_GEN' state. The following Pseudo DMA write transfer must contain the addresses of the data for the next four drawing registers. The cycle is illustrated below.

Figure 3-14: DMA General Purpose Write Sequence

**Figure 3-15: DMA Gen. Purpose Transfer Buffer Structure**

### DMA Vector Write

The first double word transferred is loaded into the Address Generator. This dw contains one bit of ‘address select’ for each of the next 32 vector vertices to be sent to the drawing registers. These 32 bits are called the vector tags. The next 32 double word transfers contain the XY address data to be written to the drawing registers.

When the tag bit is set to zero (0), the address generator will force the address to that of the XYStart register without setting the bit to start the drawing engine. When the tag bit is set to one (1), the address generator will force the address to that of the XYEnd register with the flag set to start the drawing engine.

When each dw of data is transferred, the Address Generator checks the associated tag bit and sends the appropriate 7-bit address to the Bus FIFO. When the 32<sup>nd</sup> (final) tag has been used, the next double word transfer reloads the Address Generator with the next 32 vector tags.

A direct access to a drawing register during a Pseudo DMA VECTOR resets the Address Generator state machine to the ‘LD ADR\_GEN’ state. The following Pseudo DMA write transfer must contain the vector tags for the next XY coordinate data.

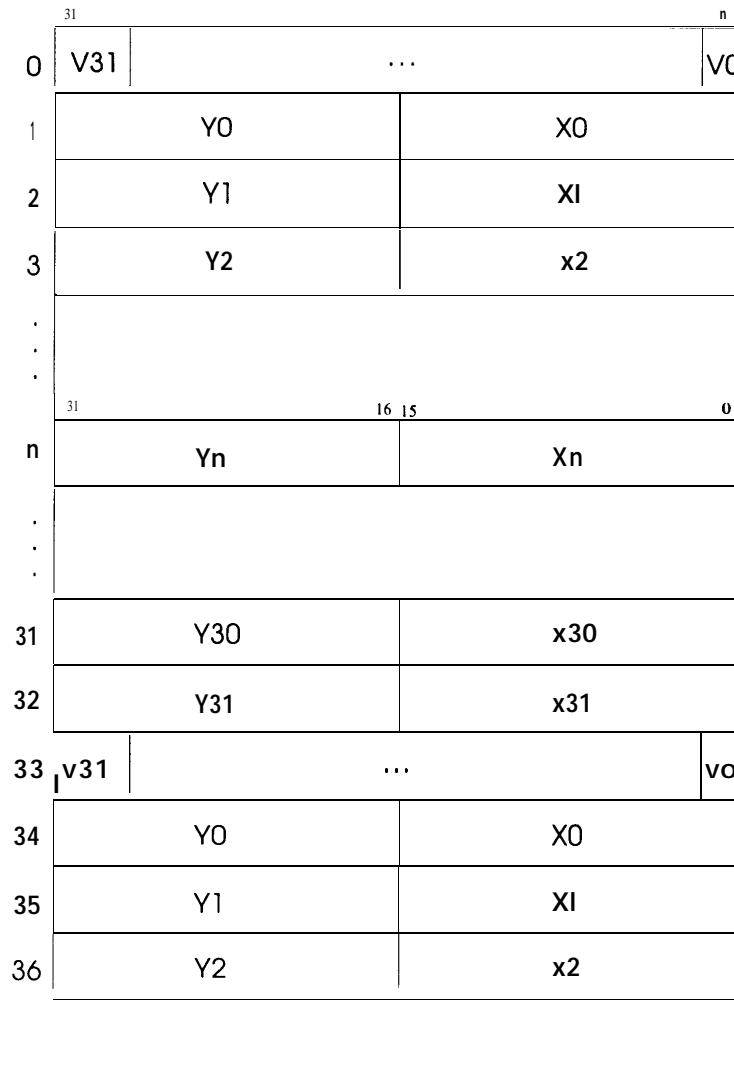

The cycle is illustrated below.

When  $V_n = 0$ ,  $add_n = XY\_START$  address (10h)

When  $V_n = 1$ ,  $add_n = XY\_END$  address + START DWG ENG (5 lh)

**Figure 3-16: DMA Vector Sequence**

**Figure 3-17: DMA Vector Transfer Buffer Structure**

## DMA BLIT Write

The DMA BLIT write is hard coded, so there's no reason to load the Address Generator. The result is that every transfer consists of data only.

When each dw of data is transferred, the Address Generator sends the srcregblit register address to the Bus FIFO. The address generator state machine is not used for this type of DMA.

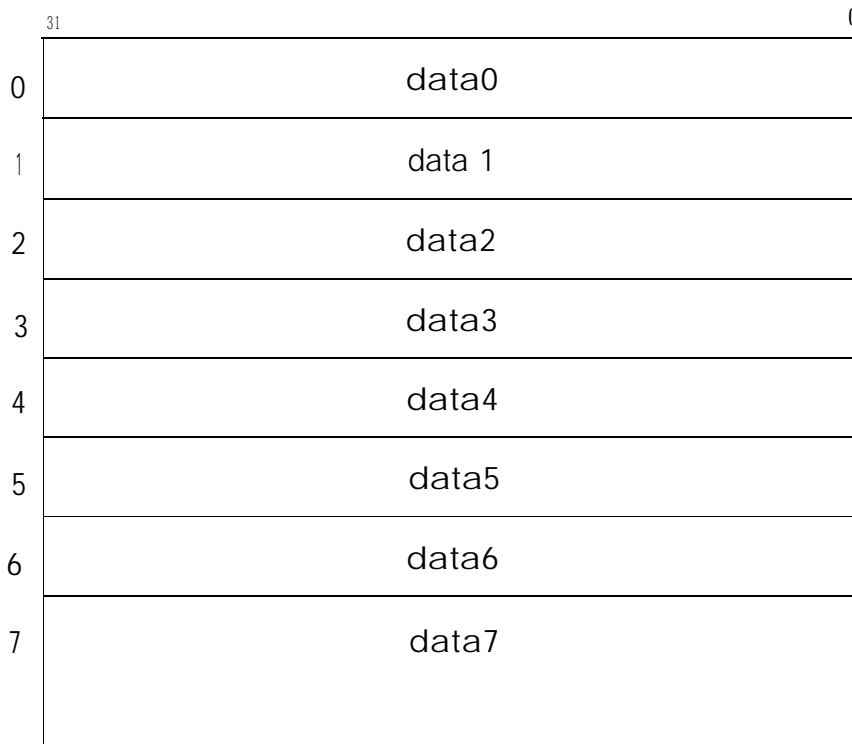

All pixels expected by the drawing engine must be transferred, otherwise it could jam. The total number of dword transfers needed to complete the BLIT operation depends on, among other factors:

- . The size of the window to be drawn (upper left corner coordinate, length in X and Y)
- . The number of bits per pixel (8, 16, or 32)

The cycle is illustrated below. No address is required for data transfer during DMA blits, so 'add' is 'don't care'.

**Figure 3-18: DMA BLIT Write Sequence**

**Figure 3-19: DMA BLIT Write Transfer Buffer Structure**

## DMA BLIT Read

As specified earlier, the DMA BLIT Read mode is available for Pseudo DMA only, and is used to dump pixels from a window of the screen to system memory. Each double word that's transferred may contain 4, 2, or 1 pixel(s), depending on the configuration (8, 16, or 32 bits per pixel, respectively).

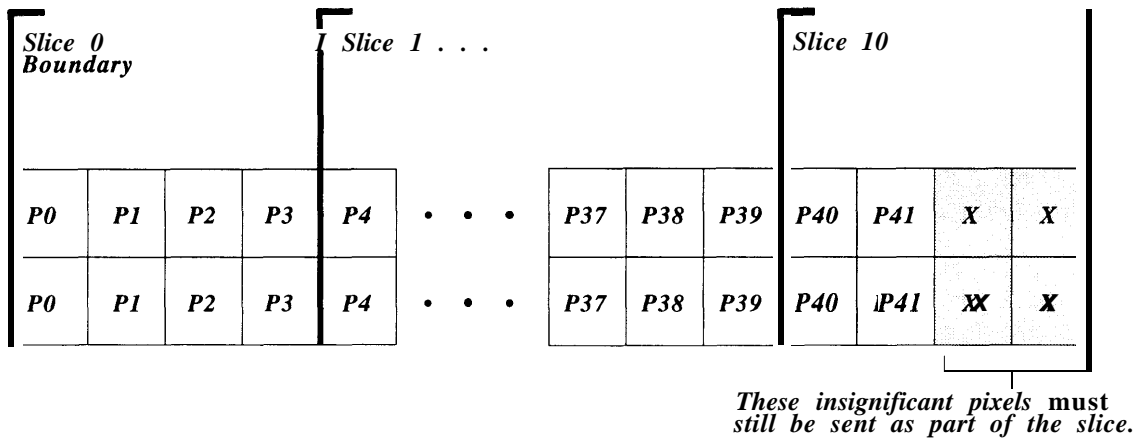

The coordinate of the upper left corner and the length in X and Y are a few of the parameters that are required by the graphic engine for this operation.

### A **Important Note:**

It is *extremely important* that the number of dwords dumped accounts for all of the pixels that are to be transferred. The last dword **for each scan line** of *pixels* may contain insignificant information in the case of 8 or 16 bit/pixel modes if the number of transferred pixels is not evenly divisible by 4 (for 8 bpp modes) or by 2 (for 16 bpp modes).

- Z.+ If the window to be drawn is not aligned at the beginning of a slice, the insignificant pixels to the left of the window are effectively disregarded, and the slice alignment begins at the start of the window.

The following illustration shows the case of an 8 bits/pixel mode transfer that is 42 pixels wide:

### 3.2.4.1 DMA

- ❖ The ATHENA chip's DMA capabilities can only be used with the AT (ISA) interface.

ATHENA supports *only* DMA I/O write transfers. The goal is use the host's DMA controller to transfer a block from the system memory into ATHENA's Bus FIFO (only the Bus FIFO is accessed during DMA write). This provides a means to write to drawing registers for specific drawing operations.

Only **16-bit** DMA transfers are supported. The total number of transfers must be an integral number of double words, to align with ATHENA's internal 32-bit data bus. The words are accumulated before sending double words to the Bus FIFO. The memory block to be transferred must be aligned on a double word boundary.

<i>isa</i>	<i>Timing Type</i>	<i>Mode</i>	<i>Data Size</i>	<i>System</i>
1	ISA Compatible	Single	16	ISA/EISA
	Type 'B'	Single	16	EISA
		Demand	16	EISA
0	Type 'B'	Single	32	EISA
		Demand	32	EISA

**Table 3-2: DMA Access Types**

To initiate a DMA transfer, take the following steps:

1. Ensure that 'dmaact' and 'pseudodma' (OPMODE register bits 1 and 0) are not active (active if '1').
2. Program the dmamod bits (OPMODE register bits 2 and 3) to one of three modes listed below (keep dmaact and pseudodma at '0'):
  - DMA General Purpose Write
  - DMA BLIT Write
  - DMA Vector Write

The function of the dmamod bits is explained later on.

3. Program the host DMA controller.
4. Start the DMA transfer by setting dmaact to '1' (keep pseudodma at '0').

Once dmaact is set, ATHENA will request DMA service by asserting DRQ. The requests will continue until the terminal count is reached. If the Bus FIFO becomes full during the DMA transfer, the request will stop automatically and resume when there is space available in the Bus FIFO.

When the DMA transfer is in progress, any access to the following devices is forbidden:

- The drawing registers (offset 1C00h-1DFFh)
  - . VRAMWIN (offset 0000h -1BFFh, vgaen = '0' and pseudodma = '0' - see Chapter 4)
  - . DMAWIN (offset 0000h - 1 BFFh, vgaen = '0' and pseudodma = '1')

Access to other MGA resources is still possible, however.

Dmaact will be automatically reset after the last transfer, when the DMA terminal count (TC) is sampled active.

DRQ is normally n-i-state. When dmaact is active, DRQ is driven to the appropriate state. This allows for resource sharing in a system with multiple MGAs. Only one MGA can have dmaact active at any time. When dmaact becomes inactive due to TC, ATHENA will have been driving DRQ low, then it will tri-state the signal.

It's possible to generate an interrupt when a DMA terminal count occurs. For more information, refer to Section 3.2.6.

### 3.2.4.2 Pseudo DMA

The goal of Pseudo DMA is the same as that of DMA, with the only difference being that read transfers are possible. Instead of using the DMA controller, Pseudo DMA transfers are 'move string' instructions in the DMAWIN memory space (offset 0000h-1BFFh, vgaen = '0' and pseudodma = '1').

Only double word accesses (read or write) are allowed in the DMAWIN memory space. When performing Pseudo DMA transfers, all of the MGA map is available, except the VRAMWIN memory space, which is disabled.

#### Write Transfers

To transfer a block of data from the system memory to the Bus FIFO of the ATHENA chip, the steps listed below must be followed:

1. Make sure that 'dmaact' and 'pseudodma' are not active.
2. Program the dmamod bits to one of the three modes listed below (keep dmaact and pseudodma at '0'):
  - DMA General Purpose Write
  - DMA BLIT Write
  - DMA Vector Write
  - a) If DMA BLIT Write is used, program all affected drawing registers. Note that all writes to the drawing registers must be double word accesses.
  - b) If DMA BLIT Write is used, send the ILOAD opcode to the drawing engine.
3. Set 'pseudodma' to '1' (keep dmaact at '0').
4. Transfer system memory data to the MGA DMAWIN memory space, with 'move string' or 'read and write' instructions.
5. Reset 'pseudodma' to '0' at the end of the block transfer.

As long as the Bus FIFO isn't full, and if the nowait bit of the OPMODE register is set to '1', then no wait will be generated for write cycles to the DMAWIN memory space. When the Bus FIFO is full, there is one more dword location, which is the Byte Accumulator of the host section. Once the Byte Accumulator and the Bus FIFO are full, the next write to the DMAWIN space will be put in waiting as long as the Byte Accumulator data isn't loaded in the Bus FIFO.

If the CHRDY ready signal is kept inactive for more than 64 gclks, the STATUS register bferrsts bit will be set. This will cause an interrupt if the proper interrupt enable is set. If CHRDY is still inactive after 128 gclks, the host section will abort the write cycle by reasserting CHRDY and by resetting the Byte Accumulator full flag.

For DMA BLIT Write operations, the drawing engine will fetch data until all pixels have been loaded, once the ILOAD opcode is sent, and if the Bus FIFO isn't empty.

## **Read Transfers**

To dump screen data to the system memory, take these steps:

1. Make sure that 'dmaact' and 'pseudodma' are not active.
2. Program the dmamod bits to DMA BLIT Read (keep dmaact and pseudodma at '0').
3. Program all affected drawing registers. Note that all writes to the drawing registers must be double word accesses.
4. Set 'pseudodma' to '1' (keep dmaact at '0').
5. Send the **IDUMP** opcode to the drawing engine.
6. Transfer data from the DMAWIN memory space to the system memory, with 'move string' or 'read and write' instructions.
7. Reset 'pseudodma' to '0' at the end of the dump.

Once the **IDUMP** opcode is sent to the drawing engine, it begins fetching pixels from the VRAMs. During a read in the DMAWIN memory space, CHRDY will be deactivated (ISA bus system), or a retry will be generated (PCI system) if the data from the drawing engine isn't ready. When the data is available, it will be latched in the host section of ATHENA, and the access is completed. A new request will be sent to the drawing engine for the next dword when the last byte, the last word, or the current dword is being read, depending on whether ATHENA is 8, 16, or 32-bit. The latched dword will be present until all bytes are read.

If the access takes more than 64 gclks, the bferrsts bit will be set in the STATUS register. This may cause an interrupt if the proper interrupt enable is set. If an access takes more than 128 gclks, the host section will abort the read cycle by reasserting CHRDY.

### 3.2.5 Programming the CRTC for Power Graphic Mode

This section explains the video parameters required for the Power Graphic display modes.

#### 3.2.5.1 Registers

In Power Graphic mode (for all resolutions and pixel depths), the video parameters that are programmed in the registers are **always** based on a video clock that is divided by 8.

- ❖ **Note:** When you change any video parameters, it is important to halt the video operation circuitry of the VRAM chips to prevent the VRAMs from entering an unrecoverable state. The ‘Screen Off’ bit in the Clocking Mode sequencer register (Address 1FC5, Index 01, Bit 5) will force the screen to blank and halt the VRAM circuitry mentioned above. This bit must be maintained to ‘off’ for at least 10  $\mu$ s after the last video parameter modification.

The CRTC\_CTRL register is used as specified. Table 3-3 shows the registers that are implicated in programming the video for the Power Graphic modes.

#### 3.2.5.2 Interlace Modes

In Power Graphic mode, the hardware can only be properly programmed in interlace modes at specific memory pitches (768, 1024, and 1280). For other pitches, the hardware must be programmed in such a way that the display area is less than the memory pitch.

It is not possible to have a horizontal resolution greater than 1280 pixels in interlace mode.

#### 3.2.5.3 Hardware Panning

Panning is achieved by programming a start address that is equivalent to the desired region. The start address is programmed in two VGA CRTC registers and one auxiliary register. Panning must be done on a multiple of 16 pixels.

#### 3.2.5.4 Hardware Zooming

Zooming by 1x, 2x, and 4x is supported.

Zooming in the X direction is performed by the clock generator. For the CRTC, this is seen simply as a division of the video clock. However, the CRTC registers that control the horizontal signals must be reprogrammed properly (relative to the divided clock) to deliver the same frequency to the monitor.

It’s important to note that if you wish to maintain a constant image between each zoom switch, the horizontal parameters must be exact multiples. For this reason, multiples of 32 must be used for each parameter (front porch, sync, etc.), even if you zoom by 1x.

To zoom in the Y direction, you must reprogram the Maximum Scan Line register in the CRTC. This will affect the way that the CRTC address counter generates line addresses.

The dt request module must also operate in non-automatic line wrap mode (refer to Bit 2 of the CRTC\_CTRL Power Graphic mode register description on page 5-61) when not zooming by 1x.

### 3.2.5.5 Programming Constraints

In order to have a correct image on the screen, you must respect different constraints when calculating the video parameters. The videodelay field of the **CRTC\_CTRL** register can be programmed for 3, 4, 5, 11, 24, or 28 videlks. The video parameters must be calculated so that at least one of the six possible values of videodelay meets the three constraints. Unexpected video results could occur otherwise.

<i>Section</i>	<i>Index</i>	<i>Name</i>	<i>D7</i>	<i>D6</i>	<i>D5</i>	<i>D4</i>	<i>D3</i>	<i>D2</i>	<i>DI</i>	<i>DO</i>

SEQ	01	Clocking Mode	X	X	S	X	X	X	X	X
		Miscellaneous Output Register	S	S	X	0	S	S	X	S

- Legend:**
- 0 The bit must always be programmed to 0
  - 1 The bit must always be programmed to 1
  - X The bit can be programmed to either 0 or 1
  - S The bit works as specified
  - Z The bit is used by the zoom in the Y direction

**Table 3-3: Power Graphic Mode Video Registers**

The following formula explains how to calculate the three constraints. The drawing engine response (in video clocks) is:

$$dw\_eng\_res = \frac{int(925ns*videofrequency+0.9)}{8}$$

Constraint #1: Videodelay  $\geq$  *Horizontal FrontPorch*+2-3

Constraint #2: Videodelay  $\geq$  *dw\_eng\_res*+1-1  $\frac{5}{8}$

Constraint #3: Videodelay  $\leq$  *Horizontal blank*+ 1-*dw\_eng\_res*-3

### 3.2.5.6 Frame Buffer Alignment

When 'No DUBIC' mode is selected, the frame buffer display must be arranged in such a way that bank switching appends during the blank (between two lines).

For example:

Assume that we want to display 1280×1024×8 using two 1MB banks. The bank transition occurs after 1M pixels:

$$\begin{array}{rcl} 1048576 & / & 1280 \\ \text{pixels} & \text{pixels/line} & \text{lines} \end{array} = 819.2$$

Round this up to 819 lines, and up-front padding will have to be added in order to ensure that the bank transition takes place between two lines:

$$\begin{array}{rcl} 1048576 & - & ( 1280 * 819) \\ \text{pixels} & & \text{pixels/line} \quad \text{lines} \end{array} = 256 \text{ pixels}$$

This means that the frame buffer will have to be started at address 256 (rather than at address 0). This produces the following results:

- . The CRTIC start address must be 256, rather than 0.
- The drawing operation must be moved by 256 pixels. This can be done automatically by the drawing engine for the destination address by initializing YDSTORG to 256. Note that this will affect the value loaded in CYBOT and CYTOP. For source addresses this adjustment will have to be done manually.
- Off-screen memory is reduced by 256 bytes.

Figure 3-20: Memory Org. (1280x1024x8 - two 1M Banks)

### 3.2.5.7 Overscan

The hardware can support the overscan feature, but using it will reduce the length of the blank period. This reduced blank will have a direct impact on your ability to meet the constraints of the video delay. It might be possible to lose the zoom feature at low resolutions, or even the integrity of the display itself if the overscan is large.

### 3.2.6 Interrupts

ATHENA supports interrupts for both ISA and PCI configurations.

- In the ISA configuration, ATHENA can generate two types of interrupts: edge interrupts, and level interrupts. The choice of interrupts is system-dependent, and is programmed by the CONFIG register's levelirq bit. In the Power Graphic modes, several interrupt sources exist:

<i><b>Interrupt</b></i>	<i><b>Description</b></i>
Bus FIFO Error Interrupt	This interrupt is generated when a cycle is aborted. It is useful during software <b>debugging</b> and testing.
DMA TC Interrupt	This interrupt is generated when a terminal count occurred at the end of a DMA transfer.
Picking Interrupt	This interrupt is generated when a pixel is written by the drawing engine.
Vertical Sync Interrupt	This interrupt is generated at every vertical sync. <i>Note:</i> The vertical sync interrupt behaves differently than the others, because two other bits must be set for it to be enabled. Bit 7 of the <b>AUX_DATA</b> register, and Bit 5 of the Vertical Retrace End register (1FB5/1FD5, Index 11) must be set before the vertical sync interrupt can be enabled. <i>Note:</i> This interrupt must be cleared by accessing Bit 4 of the Vertical Retrace End register (1FB5/1FD5, Index 11).

**Table 3-4: Interrupt Sources**

. In the PCI configuration, ATHENA uses only one interrupt line (INTA), and is a single function device. In order to integrate the DUBIC interrupts, the other external interrupts, and the current TITAN interrupt, a new register has been added.

In the PCI configuration, the interrupts must be programmed as level interrupts (levelirq) in the CONFIG register.

Three registers are used for interrupt control:

- STATUS** This register indicates the status of each of the interrupt sources.
- IEN** This register is used to individually enable each of the four interrupt sources.
- ICLEAR** ■ This register is used to individually reset each of the four interrupt sources. Note that there is no bit in this register to clear the vertical sync interrupt, which is cleared by accessing Bit 4 of the Vertical Retrace End register (1FB5/1FD5, Index 11).

### 3.3 Access Restrictions to Some Resources

Consideration must be given to several resource access restrictions (which vary depending on how the ATHENA chip is used in a system). Refer to the information on bus sizing in Sections 6.2.1.3 and 6.2.2.1.

## 3.4 Initialization and Configuration

### 3.4.1 Configuration Elements

Note: In the lists which follow, **H** indicates that a field is hard-reset. All others are soft-reset. When MGA is powered up, ATHENA's DSTx registers are loaded with the following configuration elements:

pcbrev<3:0>	rambank<8:0>	ramspeed<1:0>	expdev
product<3:0>	vgabank0	hyperpg<1:0>	tram

As well, ATHENA's host interface section receives these configuration elements:

H config<1:0>	H vgaen	H above 1 meg	<b>H</b> poseidon	<b>H</b> vbank0
H driverdy	H biosen (indirectly, H mapsel<2:0> according to vgaen)		H isa	

The following configuration elements are not programmed at power up:

ATHENA drawing engine:

mclwtst (RO)

ATHENA host interface:

ien<3:0>	H mouseen	hyperpgcl :0>*	interlace4 :0>	H vesafeat
H levelirq	H mousemap	tram*	videodelay<1:0>	
expdev*	rfhcnt<3:0>	crtcbbp<1:0>	H hrsten	
H nowait	fbm<2:0>	alw	H vrsten	

---

\* Value available in DSTO

### 3.4.2 Booting in VGA Mode

The following configuration elements from the ATHENA host interface affect the VGA, and are not programmed at power up. All the other elements are VGA-standard, and are taken care of by the BIOS.

H levelirq	H vesafeat	H hrsten	H vrsten
------------	------------	----------	----------

### 3.4.3 Booting in Power Graphic Mode

The following operations take place during the Power Graphic mode boot procedure:

1. In a PCI system, the PCI configuration space is initialized by the system boot procedure.
2. The card is detected
3. Configuration straps/switches are read
4. Depending on the configuration information and the selected hardware mode, the following non-initialized configuration elements must be programmed at power up with respect to:
  - ATHENA host interface
  - ATHENA drawing engine
  - Video interface (DUBIC if present)
  - RAMDAC
  - CLOCK GEN
  - VGA-CRTC

## 3.5 Mode Switching

### 3.5.1 Switching From VGA Mode to Power Graphic Mode

If the system has no DUBIC, disregard any step that mentions the DUBIC chip.

1. Make a call to the BIOS to select VGA Mode 3.
2. Disable VGA Mode.
  - Once the VGA has been disabled, reset the vgaen bits in ATHENA's CONFIG register.
3. Disable interrupts from DUBIC.
  - ❖ Note: If you'll be returning to Power Graphic mode later, make a note of the current value of DUBIC's DUB-SEL register.
  - Set DUBIC's DUB-SEL register to 40h.
4. Stop the enhanced mode sequencer.
  - Set the softreset bit in ATHENA's RESET register, then wait 1.5  $\mu$ sec.
5. Set DUBIC to Power Graphic mode.
  - Reset the blankdel and vga\_en bits in DUBIC's DUB-CTL register.
6. Restart the Power Graphic sequencer.
  - Reset the softreset bit in ATHENA's RESET register, then wait 1.5  $\mu$ sec.
7. Restore the value of the DUB-SEL register of the DUBIC.
8. Restart Initialization of Power Graphic mode.

### 3.52 Switching From Power Graphic Mode to VGA Mode

If the system has no DUBIC, disregard any step that mentions the DUBIC chip.

1. Disable the interrupts from DUBIC.

Note : If you'll be returning to Power Graphic mode later, make a note of the current value of DUBIC's DUB-SEL register.

- Set DUBIC's DUB-SEL register to 40h.

2. Stop the Power Graphic sequencer.

- Set the softreset bit in ATHENA's RESET register, then wait 1.5  $\mu$ sec.

3. Place DUBIC in VGA mode.

- Set the srate bit in DUBIC's DUB-CTL register. If the bus mouse is enabled, set SRATE = 18. If the laser printer port is enabled, set SRATE = 2

- Set the blankdel and vga\_en bits of DUBIC's DUB-CTL register.

4. Restart the Power Graphic mode sequencer.

- Reset the softreset bit in ATHENA's RESET register, then wait 1.5  $\mu$ sec.

5. Place the RAMDAC in VGA mode. Program the appropriate registers as shown below:

For the BT485 RAMDAC:

Command register 0 = 0000 0000 b

Command register 1 = 0000 0000 b

Command register 2 = 0000 0000 b

Command register 3 = 0000 0000 b

For the BT482 RAMDAC:

Command register A = 0000 0000 b

Command register B = 0001 1110 b

Command register C = 0000 0000 b

6. Program the Lookup Table (LUT) for VGA

7. Activate VGA Mode

- Set the vgaen and biosen bits of ATHENA's CONFIG register.

8. Restore the value of DUBIC's DUB-SEL register.

9. Make a call to the BIOS to select a VGA mode (for example: Mode 3 for text).

## 3.6 Power up and Reset

It's possible to reset ATHENA with a hard or soft reset. Both methods are explained in the following subsections.

### 3.6.1 Hard Reset

A hard reset results when a low pulse is applied to the reset pin of the ATHENA chip. The minimum pulse width required is 8  $\mu$ s.

On a hard reset, the following resources are reset:

- . VGA section
  - Drawing engine
  - Bus FIFO
- . Host section
  - All registers

As well, external configurations are loaded into registers, as appropriate.

Three rules must be followed for proper chip reset:

1. In the PCI configuration, no host access must occur within the first two PCLKs of a hard reset.
2. LDCLK, GCLK, and PCLK must be active during reset.
3. You must ensure that a PLL or clock oscillator oscillates within specifications when the power-up reset ends.

### 3.6.2 Soft Reset

A soft reset results when bit 0 of the RESET register is set to '1', then reset to '0'. On a soft reset, external strapping is not loaded.

The soft reset also initializes the Bus FIFO and all of the drawing engine. The values of the drawing registers are lost.

On the host section, some register bits are hard reset only. See Chapter 5 for more details. On the control section of the host, only three state machines are affected by the soft reset:

- IDUMP state machine
- . DMA state machine
- ADRGEN state machine

### 3.6.3 Configuring ATHENA in a Board-level Design

The ATHENA requires that configuration information be placed on the VD<63:0> bus during reset. The configuration information defines the available resources as well as the mode in which ATHENA will operate. More specifically, the following types of information are contained in the configuration bits:

- Hardware resources (memory banks, memory speed, etc.)
- Product ID and revision
- Host Interface information (Address mapping, 8/16-bit, etc.)
- Information used internally to control the operation of the ATHENA

There are two types of configuration bits:

- Soft configuration bits are read and used by software
- Hard configuration bits are loaded directly into internal registers

Upon reset, the contents of VD<31:0> are sent to DST0<31:0>; VD<63:32> is sent to DST 1 <31:0>.

- :+ Note that the destination registers must be read before any direct access to the frame buffer, or drawing engine operation is performed, in order to obtain valid data.

Configuration bus VD<63:0>

A summary of the configuration bus follows, along with a table which defines each of the configuration bits.

**Figure 3-21: Configuration Bus**

Legend:

- 0,1 Hard bits which must be set to the indicated value upon reset.
- H Hard bits which are loaded directly into internal registers upon reset.
- i Soft bits which software must read from the bus, invert, and then load into the appropriate internal register. \*
- I Hard bits which are automatically inverted and then loaded into an internal register upon reset. \*
- R Reserved bits:
- s Soft bits which software must read from the bus. These bits are not stored internally.
- S Soft bits which software must read from the bus and then load into the appropriate internal register.

Hard bits (H, I) which are loaded into other registers should be read from those destination registers, not from DST0/DST 1.

\* Since the bit is inverted, a pull-up will initialize it to 0, and a pull-down will initialize it to 1.

<i>VD Bus Bit</i>	<i>Definition</i>	<i>Hard/Soft Configuration</i>	<i>Where Used</i>
4:0	Internal	Hard (H)	Internally (See Figure 3-21 for values)
5	vgaen0	Hard (H)	Host (CONFIG<10:9>), VGA
15:6	Internal	Hard (H)	Internally (See Figure 3-21 for values)
18:16	PCB Revision	Soft (s)	Read from board
19	block8/	Soft (i)	Host (OPMODE<27>)
23:20	Product ID	Soft (s)	Read from board
24	vgabank0	Hard (H)	Host (OPMODE<11>)
32:25	rambank	Soft (s)	Read from board
34:33	ramspeed	Soft (s)	Read from board
35	rambank	Soft (s)	Read from board
36	HiRes/	Soft (s)	Read from board
37	vgaen 1	Hard (H)	Host (CONFIG<10:9>)
38	testwren	Hard (1)	Host (TEST<9>)
47:39	Internal	Hard (H)	Internally (See Figure 3-21 for values)
48	200MHz	Soft (i)	Host (CONFIG<2>)
49	nodubic<1>	Soft (i)	Host (CONFIG<5>)
50	nodubic<0>	Hard (I)	Host (CONFIG<4>)
52:51	hyperpg	Soft (S)	Host (OPMODE<25:24>)
53	expdev	Soft (S)	Host (CONFIG<16>)
54	tram	Soft (S)	Host (OPMODE<26>)
63:55	Internal (Host):		
55	isa	Hard (H)	Host (CONFIG<28>)
56	pci	Hard (I)	Host (CONFIG<27>)
57	above 1 meg	Hard (I)	Host (CONFIG<12>)
58	driverdy	Hard (I)	Host (CONFIG<8>)
61:59	mapsel	Hard (H)	Host (CONFIG<26:24>)
63:62	config	Hard (H)	Host (CONFIG<1:0>)

**Table 3-5: Strapping Definition: ATHENA-based Design**

Note: To ensure compatibility with future software, bits VD<49:48> and VD<39> should be enabled high ('1') during reset.

### 3.6.3.1 Special Considerations for PCI

Since the coarse decoding is done by the PCI interface module, the host-module decoding section of ATHENA is not used. This means that ATHENA will always be configured the same way:

<i>Register Bits</i>	<i>VD Bit</i>	<i>Inversion</i>	<i>Strapping</i>
config<1>	63	No	PD
config<0>	62	No	PD
mapsel<2>	61	No	PD
mapsel<1>	60	No	PU
mapsel<0>	59	No	PD
driverdy	58	Yes	PD
above1meg	57	Yes	PU
pci	56	Yes	PD
isa	55	No	PD
vgabank0	24	No	PD
vgaen0	5	No	PD

### 3.6.4 Reset Field Definitions

The reset fields listed in the Table 3-5 are explained in detail below:

**Internal** These bits are read from VD<4:0> on reset. These lines must present the value 19h during reset.

**vgaen<1:0>** DST<5>,CONFIG<10> VGA enable. Refer to the CONFIG register description in Chapter 5 for more details.

VGAENO and VGAENI are used to enable/disable the VGA. Only one bit is used at a time (the other one is tied to GND). The following table shows how the internal bits are initialized at reset:

- . When VGAENO is used, the 46E8 feature is enabled when the VGA is turned on.
- When VGAENI is used, the 46E8 feature is not enabled with the VGA. VGAENI should be used with the PCI interface, since PCI incorporates auto-configuration which may cause problems with the fixed decoding of the 46E8 feature.

<i>VGAENI</i>	<i>VGAENO</i>	<i>en46E8</i>	<i>CONFIG&lt;10,9&gt;</i>	
0	0	0	0	0
0	1	1	1	1
1	0	0	1	1

This field is read from VD<37,5>.

**Internal** This field is read from VD<15:6> on reset. These lines must present the value 027h during reset.

**PCB  
Revision**

DST0<18:16> Indicates the revision of the PCB. Refer to the DST1-0 register description in Chapter 5 for more details.

<i>Value</i>	<i>PCB Revision Level</i>
111h	0
110h	1
:	:

These bits are read from VD<19:16> on reset.

**block8/  
<19>**

OPMODE<27>. Indicates VRAM support for 8-bit block mode transfers.

Refer to the OPMODE register description in Chapter 5 for more details.

**Product ID**

DST0<23:20> Indicates the Product ID/Platform. Refer to the DST1-0 register description in Chapter 5 for more details.

<i>Product ID</i>	<i>Product Platform</i>
11xx	ISA Bus
101x	VL Bus
100x	MCA Bus
0110	PCI Bus
0111	Reserved (do not use)
0101	To be defined (future platforms)
:	
:	
0000	

These bits are read from VD<23:20> on reset.

**vgabank0**

OPMODE<11> VGA Bank 0. Refer to the OPMODE register description in Chapter 5 for more details.

This bit is read from VD<24> on reset, and stored here.

**rambank  
<8:0>**

DST1<0>, DST0<31:25> DST1<3> indicates the presence (when '1') of Banks 1-8. Refer to the DST1-0 register description in Chapter 5 for more details.

<i>Value</i>	<i>Bank</i>	<i>Description</i>
xxxxxxxxx1	0	8 x 128K x 8 VRAM
xxxxxxxx1x	1	8 x 128K x 8 VRAM
xxxxxx1xx	2	6 or 8 x 256K x 8 VRAM
xxxxx1xxx	3	6 or 8 x 256K x 8 VRAM
xxxx1xxxx	4	6 x 256K x 8 VRAM
xxx1xxxxx	5	4 x 256K x 16 DRAM - Reserved
xx1xxxxxx	6	Reserved
x1xxxxxxx	7	2 x 128K x 8 DRAM - Patch DRAM
1xxxxxxxx	8	4 x 64K or 256K x 16DRAM

These bits are read from VD<32:25>, VD<35> on reset.

**ramspeed  
<1:0>**

DST 1<2:1> Indicates the speed of the on-board memory. Refer to the DST 1-0 register description in Chapter 5 for more details. These bits are read from VD<34:33> on reset.

Note: *All memory must be the same speed.*

<i>Value</i>	<i>Memory Speed</i>
11h	-80 (80 nanosecond access time)
Others	Reserved

**HiRes/**

DST1<4> Indicates that the board is capable of displaying at a resolution of 1600 x 1200. Refer to the DST 1-0 register description in Chapter 5 for more details.

<i>Value</i>	<i>Meaning</i>
0	Board supports 1600 x 1200
1	Board does not support 1600 x 1200

This bit is read from VD<36> on reset

**testwren**

DST 1 <6> Must be pulled up. See the TEST register description on page 5-50 for more details. This bit is read from VD<38> on reset.

**Reserved**

These bits, which are read from VD<39> on reset, should be pulled high during reset.

**Internal**

These lines are read from VD<47:40> on reset. They must present the data DFh during reset.

**200MHz**

This bit indicates the presence of a 200 MHz RAMDAC. Refer to the CONFIG register description in Chapter 5 for more details.

<b>nodubic &lt;1:0&gt;</b>	CONFIG<5:4>. These bits indicate the configuration of the VRAM serial port. Refer to the CONFIG register description for more details.
<b>hyperpg</b>	OPMODE<25:24> Support for Hyper Page mode. Refer to the OPMODE register description in Chapter 5 for more details.  These bits are read from VD<52:51> during reset. Software must read these bits from DST1<20:19> and load them here.
<b>expdev</b>	CONFIG<16> Expansion device. Refer to the CONFIG register description in Chapter 5 for more details.  Read from VD<53> during reset. Software must read this bit from DST1<21> and load it here.
<b>tram</b>	OPMODE<26> Type of VRAM. Refer to the OPMODE register description in Chapter 5 for more details.  Read from VD<54> during reset. Software must read this bit from DST1<22> and load it here.
<b>isa</b>	CONFIG<28> ISA bus identification. Refer to the CONFIG register description in Chapter 5 for more details.  Sampled from VD<55> on reset, this bit assumes the external strapping configuration value.
<b>pci</b>	CONFIG<27> In conjunction with the isa bit, determines the type of host interface. Refer to the CONFIG register description in Chapter 5 for more details. The value sampled from VD<56> on reset is inverted and stored in this bit.
<b>abovelmeg</b>	CONFIG<12> Mapped above 1 MB. Refer to the CONFIG register description in Chapter 5 for more details. The value sampled from VD<57> on reset is inverted and stored in this bit.
<b>driverdy</b>	CONFIG<8> Drive channel ready. Refer to the CONFIG register description in Chapter 5 for more details. The value sampled from VD<58> on reset is inverted and stored here.
<b>mapsel &lt;2:0&gt;</b>	CONFIG<26:24> Select base address of MGA board in system. Refer to the CONFIG register description in Chapter 5 for more details. The value is sampled from VD<61:59> on reset and loaded here.
<b>config</b>	CONFIG<1:0> Configuration bits. Refer to the CONFIG register description in Chapter 5 for more details. This value is sampled from VD<63:62> on reset and loaded here.

---

## **Chapter 4: Memory Mapping**

***T***his chapter summarizes the memory map for the ATHENA in both the ISA and PCI configurations, and provides an overview of the I/O space mapping for the VGA I/O and mouse port registers.

## 4.1 ISA and PCI Configurations

The ATHENA chip supports two bus configurations: PCI (Peripheral Component Interconnect) and ISA (Industry Standard Architecture, often called ‘AT-bus’). The major differences between these configurations are that the ATHENA memory mapping is different for PCI, and the PCI configuration includes space that is reserved for system configuration (the ISA configuration has no ‘configuration space’).

### 4.1.1 Configuration Space Mapping

The configuration space is supported only for PCI devices. When modes other than PCI are selected, this space (and its registers) are invisible and unused. The entire configuration space is decoded by ATHENA.

<i>Offset (1)</i>	<i>Name</i>	<i>Access</i>	<i>ResetValue</i>							
00	DEVID	R	0000	1101	0001	0000	0001	0000	0010	1011b
04	DEVCTRL	R/W	0000	0100	0000	0000	0000	0000	1000	0000b
08	CLASS	R	0000	0011	0000	0000	0000	0000	0000	0000b
0c	HEADER	R	0000	0000	0000	0000	0000	0000	0000	0000b
10	TERMBASE	R/W	0000	0000	0000	0000	0000	0000	0000	0000b
30	ROMBASE	R/W	0000	0000	0000	0000	0000	0000	0000	0000b
c3	INTCTRL	R/W	0000	0000	0000	0000	0000	0001	1111	1111b
40	OPTION	R/W	0000	0000	0000	0000	0000	0000	0000	0000b

**Table 4-1: ATHENA Configuration Space Mapping**

## 4.2 Memory Space Mapping

### 4.2.1 ISA Interface

All extensions to Power Graphic mode are mapped in the memory space, as well as in the VGA frame buffer and in the VGA BIOS.

<i>Address</i>	<i>Device Decoded</i>	<i>Condition (1)</i>
0A0000h-0BFFFFh	VGA frame buffer	If vgaen is active.
0C0000h-0C7FFFh	VGA BIOS ROM	If biosen is active.
0AC000h-0AFFFFh	MGA Power Graphic Mode	If MAPSEL1 is selected and the VGA is either disabled or VMAPSEL = 1 (2)
0C8000h-0CBFFFh	”	If MAPSEL2 is selected.
0CC000h-0CFFFFh	”	If MAPSEL3 is selected.
0D0000h-0D3FFFh	”	If MAPSEL4 is selected.
0D4000h-0D7FFFh	”	If MAPSEL5 is selected.
0D8000h-0DBFFFh	”	If MAPSEL6 is selected.
0DC000h-0DFFFFh	”	If MAPSEL7 is selected.

**Table 4-2: ATHENA ISA Interface Memory Mapping**

(1) Refer to the CONFIG register description in Chapter 5 for information on the control bits used to select the map options.

(2) VMAPSEL is located at I/O address 3CF, Index 6, Bit 3.

Refer to Table 4-4 for the Power Graphic Mode memory mapping for both the ISA and PCI interfaces.

## 4.2.2 PCI Interface

The memory mapping for PCI mode is shown below:

<i>Address Offset Range</i>	<i>Device Decoded</i>	<i>Condition</i>
000A0000h-000BFFFFh	VGA Frame Buffer	If vgaen and memspace are active
nnnn0000h-nnnn7FFFh or nnnn8000h-nnnnFFFFh	VGA BIOS ROM (1)	If biosen and memspace are active
mmmm0000h-mmmm3FFFh or mddd4000h-mddd7FFFh or mddd8000h-mdddBFFFh or mdddC000h-mdddFFFFh	MGA Power Graphic Mode (2)	If memspace is active

**Table 4-3: ATHENA PCI Interface Memory Mapping**

(1) The exact location in the memory space depends on the ROMBASE register. Because ATHENA is decoded as a VGA device, the ROM should be mapped at 000C0000h by the system BIOS as specified in the *PCI Bus Specification*.

(2) The exact location in the memory space depends on the TERMBASE register.

## 4.2.3 Power Graphic Mode Mapping (ISA and PCI)

<i>Address Offset Range</i>	<i>Condition</i>	<i>R/W</i>	<i>Mnemonic</i>	<i>Device Decoded</i>
0000h-1 BFFh	VgaEn/ & PseudoDma/	R/W	VRAMWIN	7K VRAM window
0000h-1 BFFh	VgaEn/ & PseudoDma	W	DMAWIN	7K Pseudo-DMA window (1)
0000h-1 BFFh	VgaEn/ & PseudoDma	R	IDUMP	7K Pseudo-DMA window (1)
1 C00h-1 FFFh		R/W	INTREG	ATHENA internal registers (2)
2000h-3BFFh	VgaEn/ & PseudoDma/	R/W	Reserved	7K VRAM window (redundant) Reserved
3C00h-3C7Fh		R/W	RAMDAC	RAMDAC (3)
3C80h-3CFFh		R/W	DUBIC	DUBIC (3)
3D00h-3D7Fh		R/W	VIWIC	VIWIC (3)
3D80h-3DFFh	ExpDev/	W	CLKGEN	EXPSL/ (3)
3D80h-3DFFh	ExpDev	R/W	CLKGEN	EXPSL/ (3)
3E00h-3FFFh	ExpDev	R/W	EXPDEV	EXPSU (3)

**Table 4-4: ATHENA Power Graphic Mode Memory Mapping**

- Refer to Section 3.2.4.2, 'Pseudo DMA', for more information.
- Refer to the following tables for definitions and specific addresses of the ATHENA internal registers.
- In the external device range, all devices are double-word aligned and only accessible on byte 0. Only byte 0 accesses are allowed. Word and double-word accesses will cause unpredictable results.

<i>Offset (1)</i>	<i>Name</i>	<i>Category (2)</i>	<i>Access</i>	<i>ResetValue</i>
1C00	DWGCTL	F	W	0000 0000h
1C04	MACCESS	F	W	0000 0000h
1C08	MCTLWTST	F	W	FFFF FFFFh
1C10	DSTI-0	D	R	Loaded from vd<63:0>
1C18	ZMSK	F	W	XXXX XXXXh
1C1C	PLNWT	F	W	XXXX xxxxxh
1C20	BCOL	F	W	XXXX XXXXh
1C24	FCOL	F	W	xxxx xxxxxh
1C30	SRCO-3	FD	W	XXXX XXXXh
1C40	XYSTRT	FKD	W	xxxxxxxxxxh
1C44	XYEND	FKD	W	XXXX XXXXh
1C50	SHIFT	FKD	W	XXXX xxxxxh
1C58	SGN	FKD	W	xxxxxxxxxxh
1C5C	LEN	FKD	W	XXXX XXXXh
1C60	AR0	FKD	W	XXXX XXXXh
1C64	AR1	FKD	W	XXXX XXXXh
1C68	AR2	FKD	W	XXXX XXXXh
1C6C	AR3	FKD	W	XXXX XXXXh
1C70	AR4	FKD	W	XXXX XXXXh
1 c74	AR5	FKD	W	XXXX xxxxxh
1C78	AR6	FKD	W	XXXX XXXXh
1C8C	PITCH	FK	W	XXXX XXXXh
1C90	YDST	FKD	W	(7)
1C94	YDSTORG	FK	W	XXXX XXXXh

**Table 4-5: ATHENA Register Mapping**

**Notes:**

Any location within the 1C00h–1FFFh offset range that is not identified in Table 4-5 should be considered as reserved.

(1) The address offsets provided are relative to the MGA Power Graphic mode base memory address, as shown in Table 4-2.

(2) The **Category** refers to the special characteristics of each register. The following categories are defined:

- D This register is a drawing engine dynamic register. This means that the contents of the register may be modified by a drawing cycle. You must wait until the drawing engine is idle before you can read dynamic registers.
- F The data for this register is passed through the Command FIFO. The Command FIFO contents are sent to the drawing engine only when it is ready to use them. This is the method used to synchronize the software with the drawing engine (no access to drawing engine registers should be attempted when the FIFO is full). This means that it is guaranteed that a register will be written only when the FIFO is empty. A register should only be read when the FIFO is empty, in order to be sure that the contents of that register are stable.
- K These registers can be initialized when the memory sequencer is not idle. It is then preferable to initialize them first (when required) in order to achieve higher performance.
- V These BYTE registers are in the VGA module. They are accessed in the same way as the VGA I/O port, except that they are memory mapped.

(3) When a register is accessed in this range, this indicates to the drawing engine to start a drawing cycle.

(4) A read from port 1FBA/1FDAh resets this port to the Attributes Address register. The first read or write to this register after a 1FBA/1FDAh reset accesses the attributes index, and the next read or write accesses the palette. Subsequent reads or writes to this register toggle between index and palette.

(5) D0=0 of the MISC-OUT register sets the CRTC registers to 1FBXh and the input status 1 to 1FBA. D0=1 of the MISC-OUT register sets the CRTC registers to 1FDXh and the input status 1 to 1FDAh.

(Notes continue on the next page)

- (6) See the VGA\_SUBSYS register description for more information.
- (7) **Reset Values.** The following table lists register reset values that were too wide for the previous table:

<i>Byte Offset (1)</i>	<i>Name</i>	<i>Reset Value</i>
1C90	YDST	XXXX XXX0 XXXX XXXX XXXX XXXX XXXX XXXX b
1E44	TEST	0000 0000 0000 0000 0000 0000 0000 0000 0000 b
1E50	CONFIG	000H HHHH 0000 0000 000H 000H 0000 000H b
1E54	OPMODE	0000 0000 0000 0000 0000 H000 0000 0000 b

**Legend**

X = Undefined  
H = Sampled on hard reset

- (8) Alternate addresses of 1FB4h/1FD4h.
- (9) Alternate addresses of 1FB5/1FD5h.
- (10) This register only exists in the PCI configuration.

## 4.3 I/O Mapping

Two different devices are mapped in the I/O space: the VGA I/O registers, and the mouse port. The I/O mapping remains the same for the ISA and PCI configurations.

Port	Name	Access	Decoded as:			
			Hercules	CGA	EGA	VGA
238h	Mouse data register (6)	R				
23Ah	Mouse control register (6)	R/W				
23Bh	Mouse configuration register (no write effect) (6)	W

**Table 4-6: I/O Mapping**

- (1) A read from Port 3BA/3DAh resets this port to the attributes address register. The first read/write to this register after a 3BA/3DAh reset accesses the attributes index, and the next read/write accesses the palette. Subsequent reads or writes to this register toggle between index and palette.
  - (2) D0=0 of the miscellaneous output register sets: CRTC registers to 3BXh; input status 1 to 3BA. D0=1 of the miscellaneous output register sets: CRTC registers to 3DXh; input status 1 to 3DA.
  - (3) Alternate addresses of 3B4/3D4h.
  - (4) Alternate addresses of 3B5/3D5h.
  - (5) In the PCI configuration, these locations are only decoded for write operations. Snooping is always enabled. In the ISA configuration, these locations are decoded only when the 'VGAENO' bit is sampled active on reset, otherwise, they are not decoded.
  - (6) For more details refer to the OPMODE register description for bits 8 and 9 contained in Chapter 5. Refer to the *MGA DUBIC Specification* for more information about these registers.
  - (7) In the PCI configuration, snooping is enabled on these locations if 'vgasnoop' is active. Otherwise, normal access is performed.
  - (8) In the PCI configuration, external expansion space is never enabled during an I/O cycle.
- ❖ Note that the 3B0–3BB, 3BF–3C5, and 3CA–3DF ranges are always decoded when VGA is enabled, even when there is no register located at a specific address. The 3BC–3BE range is never decoded.

---

## **Chapter 5: Register Descriptions**

**T***his chapter contains a description of each of the Power Graphic and VGA mode registers of the ATHENA chip, listed in address order for each mode.*

*Note that Tables 4-5 and 4-6 list all of the registers in address order. In addition, lists of all registers (and the Power Graphic mode register fields) are presented in alphabetical order at the back of this manual.*

# 5.1 Register Descriptions

## 5.1.1 Power Graphics Mode Registers

### SAMPLE\_PG Sample Power Graphic Mode Register Description

- field1**            FIELD1 . Detailed description of the <field1> field, which comprises bits <22:0> 22 to 0.
- field2**            FIELD2. Detailed description of the <field2> field, which is bit 23.
- field3**            FIELD3. Detailed description of the <field3> field, which comprises bits <26:24> 26 to 24.
- Reserved**        Reserved: Writing has no effect.

Power Graphic Mode register descriptions contain a (double-underlined) header which indicates the register’s mnemonic abbreviation and its full name. Below the header, the memory address (1C00 for example), attributes, and reset value for the register are provided. Next, an illustration of the register identifies the locations of all the bits, which are then described in detail below the illustration.

#### Memory Address

The addresses of all the Power Graphic mode registers are provided in Chapter 4.

#### Attributes

The Power Graphic mode attributes are:

- R: Read Only
- W: Write Only
- R/W: Read and Write
- D: Dynamic. The contents of the register may be modified by a drawing cycle. Before such registers can be read, the drawing engine must be idle.
- F: FIFO. Data for this type of register is passed through the Command FIFO. The contents of the Command FIFO are used by the drawing engine only when the drawing engine is ready to access them. This is the method used to synchronize the software with the drawing engine (no **access to the drawing engine registers should be attempted when the FIFO is full**). This also means that a register is guaranteed to be written only when the FIFO is empty. The drawing engine registers should only be read when the FIFO is empty to make sure that the contents of the register are stable.
- K: These registers can be initialized when the memory sequencer isn’t idle, so it’s preferable to initialize them first (when required) to achieve higher performance.

## Reset Value

The reset values for the Power Graphic mode registers can be expressed as hexadecimal or binary values. Most bits are reset on both soft and hard reset. Some bits are reset on hard reset only (those bits are underlined when they appear in the register description header next to **Reset Value**).

- 000X 0000h (h = Hexadecimal)
- 0000 0000 0X00 00HO 0000 0000 0000 0000b (b = Binary)

Legend:

X= Undefined

H = Sampled on hard reset

## 5.1.2 VGA Mode Registers

### Sample VGA Mode Register Description

**SAMPLE\_VGA**

Memory Address <addr>	I/O Address <addr>	Index <index>
Reserved	D5 D4	D3-D2 D1 D0
I	I w - - - - - I I	
7	6	5
4	3	2
1	0	

**D0** A detailed description of the function of data bit 0.

**D1** A detailed description of the function of data bit 1.

**D3-D2** A detailed description of the function of the data field which contains bits 2 and 3, etc.

ATHENA VGA Mode register descriptions contain a (single-underlined) header which indicates the register's name and type (such as CRT Controller or Sequencer, etc.). Below the header, the memory address (1 COO for example), I/O address, and the offset index for the register are indicated. Next, an illustration of the register identifies the locations of all the bits, which are then described in detail below the illustration.

### Memory Address

This address is an offset from the Power Graphic mode base memory address. The memory addresses can be read, write, color, or monochrome, as indicated. Note that some of the VGA mode registers have no memory address and some have no index.

### I/O Address

These addresses are I/O ports. The I/O addresses can be read, write, color, or monochrome, as indicated.

### Index

This is the indexed address of the specific register.

## 5.2 Power Graphic Mode Register Descriptions

DEVID

Device ID

Configuration

Space Address 00

Attributes R

Reset Value 0000 1101 0001 000000010000 0010 1011b

**device**  
**<31:16>**

DEVICE identifiers. The data is the 5-bit ASCII code for the first three characters of the string: "ATHENA".

**vendor**  
**<15:0>**

The Matrox VENDOR identifier for PCI: 0x102B.

Configuration

Space Address 04

Attributes R/W

Reset Value 0000 0100 0000 0000 0000 0000 1000 0000b

- Reserved**  
<31:27>

Reserved: This field is always read as 0.
- devselm R**  
<26:25>

DEvICE SElect TIMing. Specifies the timing of devsel. It is read as 01.
- Reserved**  
<24:8>

Reserved: This field is always read as 0.
- waitcycle R**  
<7>

WAIT CYCLE: Specifies that ATHENA will perform continuous address/data stepping. This bit is always read as 1.
- Reserved**  
<6>

Reserved: This field is always read as 0.
- vgasnoop R/W**  
<5>

VGA SNOOPing. Controls how ATHENA will handle access to the PCI system palette register (as described in Section 3.10 of the *PCI Local Bus Specification*, Revision 2.0).

  - . 0: Respond to a palette access.
  - 1: Enable special snooping behavior.
- Reserved**  
<4:2>

Reserved: This field is always read as 0.
- memspace R/W cl**

Device response to MEMory SPACE access. This bit controls all memory spaces (EPROM, VGA frame buffer, and Power Graphic mode memory space).

  - 0: Disable the device response
  - 1: Enable the device response
- iospace R/W <0>**

Device response to I/O SPACE access. This bit controls all I/O space (VGA I/O, and Mouse port).

  - 0: Disable the device response
  - 1: Enable the device response

Configuration  
Space Address 08

Attributes R

Reset Value 0000 0011 S000 0000 0000 0000 0000 0000b

**class<31:9>** Device CLASS. Identifies the generic function of the device and a specific register-level programming interface according to the PCI specification. Two values can be read in this field according to the value of the CONFIG register's vgaen field in the host interface:

<i>vgaen</i>	<i>Value</i>	<i>Meaning</i>
0	038000h	Other display controller
1	030000h	Super VGA-compatible controller

**revision<8:0>** REVISION. Contains the current board revision. This value is always read as 0.

HEADER

Header

Configuration  
Space Address 0C

Attributes R

Reset Value 0000 0000 0000 0000 0000 0000 0000 0000b

**Reserved<31:24>** Reserved: This field is always read as 00h.

**header<23:16>** HEADER layout. Specifies the layout of bytes 10h through 3Fh in the configuration space. Also specifies that the current device is a single function device. This field is always read as 00h.

**Reserved<15:0>** Reserved: This field is always read as 0000h.

**Terminator Base Address**

**TERMBASE**

**Configuration**

**Space Address 10**

**Attributes R/W**

**Reset Value** 0000 0000 0000 0000 0000 0000 0000 0000b

**termbase**  
**<31:14>**

TERMinator (Power Graphic) BASE Address. Specifies the base address of the Power Graphic mode memory space. Mapping in this 16KB space is decoded by ATHENA itself. Refer to Chapter 4 for more information.

**Reserved**  
**<13:0>**

Reserved: This field is always read as 0.

**ROM Base Address**

**ROMBASE**

**Configuration**

**Space Address 30**

**Attributes R/W**

**Reset Value** 0000 0000 0000 0000 0000 0000 0000 0000b

**rombase**  
**<31:15>**

EPROM BASE address. Specifies the base address of the EPROM. This field's attribute changes, depending on the value of the CONFIG register's biosen field:

<i>biosen</i>	<i>ROMBASE Attribute</i>
0	RO. Read as 0
1	R/W

**Reserved**  
**<14:1>**

Reserved: This field is always read as 0000h.

**romen<0>**

ROM ENable. Enable the ROM. This field's attribute changes, depending on the value of the CONFIG register's biosen field:

<i>biosen</i>	<i>ROMEN Attribute</i>
0	RO. Read as 0
1	R/W

**Configuration**

Space Address 3C

Attributes R/W

Reset Value 000000000000000000000001 1111 1111b

**Reserved** Reserved: This field is always read as 0000h.  
**<31:16>**

**intpin R** Selected INTerrupt PINs. This field is always read as lh, since INTA is used as the  
**<15:8>** interrupt pin.

**intline R/W** INTerrupt LINE routing. This R/W field is used to communicate interrupt line routing  
**<7:0>** information. It is initialized at power-up to identify for the device drivers which device interrupt pin has been connected to which system interrupt controller pin. The value FFh is defined as 'unknown' or 'no connection' to the interrupt controller.

**Configuration**

**Space Address** 40

**Attributes** R/W

**Reset Value** 0000 0000 0000 0000 0000 0000 0000 0000b

Reserved  
<31:2>

Reserved: This field is always read as 0000h.

**speed**<1:0>

SPEED. This field is used to select the sequence access on the TAD bus, depending on the current PCI bus speed. This field only affects the 0000-1FAF and 1FE0-3FFF ranges in the 16K window.

speed	pciclk MHz	cmd: time (#clk):(ns)	!cmd: time (#clk):(ns)	cycle: time (#clk):(ns)
00	<b>33</b>	<b>3.5</b> : 105	<b>2.5</b> : 75	<b>6</b> : 180
01	<b>33</b>	<b>3.0</b> : <b>90</b>	<b>2.0</b> : 60	5 : 150
01	<b>25</b>	<b>3.0</b> : <b>120</b>	<b>2.0</b> : <b>80</b>	5 : 200
10	<b>25</b>	<b>2.5</b> : 100	1.5 : 60	4 : 160
11	Reserved			

Memory Address 1C00

Attributes W-F

Reset Value 0000 0000 h

**opcode**  
**<3:0>**

Operation CODE: The opcode field defines the operation selected by the drawing engine, and also affects the operation of the VRAM interface section.

Function	Subfunction	opcode	
		Value	Mnemonic
Line		0000	LINE-OPEN
	AUTO	0001	AUTOLINE-OPEN
	WRITE LAST	0010	LINE-CLOSE
	AUTO, WRITE LAST	0011	AUTOLINE CLOSE
Trapeziod		0100	TRAP
Bitblit	VRAM -> VRAM	1000	BITBLT
	HOST -> VRAM	1001	ILOAD
	VRAM -> HOST	1010	IDUMP

All other opcodes are reserved and should not be used.

**atype**  
**<5:4>**

Access TYPE: The atype field is used to define the type of access to the VRAM that is performed.

atype		VRAM Access
Value	Mnemonic	
00	RPL	Write (replace)
01	RSTR	Read modify write (raster)
10	ANTI	Anti-aliased
11	ZI	Depth mode with Gouraud shading

**blockm**  
**<6>** BLOCK Mode: Specifies whether or not the destination will be written in block mode.

- 0 Normal write access
- . 1 Block mode write selected

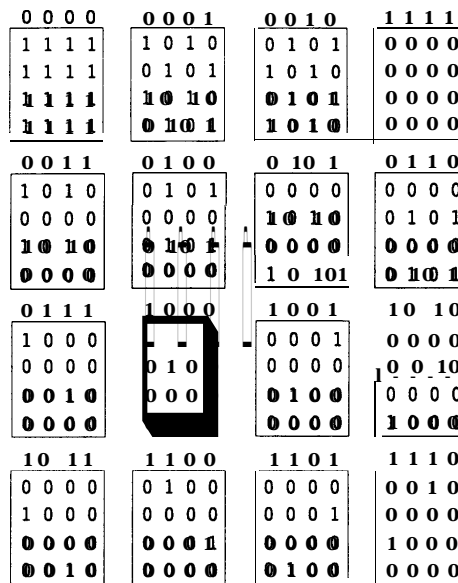

**linear**  
**<7>** LINEAR mode: Specifies if the BITBLIT source is linear or XY.

- . 0 XY bitblit
- 1 Linear bitblit

**bop**  
**<19:16>** Boolean Operation between a source and a destination. The table below shows the various functions performed by the Boolean ALU in 1, 8, 16, and 32 bits/pixel modes. During block mode operations, bop must be set to 1100 (Ch).

<i>bop</i>	<i>Function</i>
<b>0000</b>	<b>0</b>
0001	-(D I S)
0010	D & - S
0011	-S
0100	(-D) & S
0101	-D
0110	D ^ S
0111	-(D & S)
1000	D & S
1001	-(D ^ S)
1010	D
1011	D I -S
1100	S
1101	(-D) I S
1110	DIS
1111	

**trans**  
**<23:20>** TRANSlucidity: Specifies the percentage of opacity of the object. The opacity is realized by writing one over ‘n’ pixels. The trans field specifies the following transparency patterns (where 1 is opaque and 0 is transparent):

**alphadit**  
<24>

ALPHA DIThering and shading enabled : Specifies whether the RED shader is used to generate the Alpha channel in 32 bits/pixel mode.

- 0: forcol<31:24> is used
- . 1: DR5<28:15> is used

**bltmod**  
<26:25>

BLIT MODE selection: This field must be valid for BLITs without anti-aliasing:

<i>bltmod</i>		<i>Usage</i>
<i>Value</i>	<i>Mnemonic</i>	
00	BMONO	Source operand is monochrome in 1 bits/pixel .
01	BPLAN	Source operand is monochrome from one plane.
10	BFCOL	Source operand is color. Source is formatted when it comes from the host. Fast clipping can be used during VRAM to VRAM BLITs.
11	BUCOL	Source operand is color. Source is in 32 bits/pixel when it comes from the host. Fast clipping can't be used during VRAM to VRAM BLITs.

This field must contain the value BFCOL in order to handle the line style properly for line drawing using line style.

**zdrwen**  
<25>

Z DRaW comparison ENabled: This field is shared with another field (see bltmod, above). It must be valid for drawing using depth. This bit specifies whether or not Z comparison is used.

- 0 Don't use depth comparison
- 1 Use depth comparison

- zlte**  
**<26>** Z written when Less Than or Equal: This field is shared with another field. It must be valid for drawing using depth. This bit specifies whether Z is written when it is equal.
- . 0 Pixel is updated if depth is <
  - . 1 Pixel is updated if depth is  $\leq$
- afor**  
**<27>** Anti-aliasing **FO**Reground color selected: This field is shared with the hgbr field. It must be valid when anti-aliasing is selected. This bit performs the first color selection for the anti-aliasing.
- 0 DR5<22:15>, DR9<22:15>, and DR 13<22:15> are used
  - 1 FORCOL<23:0> is used
- hbgr** **<27>** Host data in BGR format: This field is shared with the afor field.
- For ILOAD when bltmod = BUCOL
- 0 Source data is in BGR format
  - . 1 Source data is in RGB format
- For ILOAD when bltmod = BMONO
- 0 Source data is in endian format
  - . 1 Source data is in Windows format
- abac**  
**<28>** Anti-aliasing **BAC**kground color selected: This field is shared with the hcprs field. It must be valid when anti-aliasing is selected. This bit performs the second color selection for the anti-aliasing.
- 0 Current pixel is selected
  - 1 BACKCOL<23:0> is selected

---

---

<b>hcprs</b> <b>&lt;28&gt;</b>	Host data is <b>ComPReSsed</b> : This field is shared with the <b>abac</b> field. It must be valid for color <b>BLITs</b> when the source data comes from the host and the data is in 24-bit true color format.  . 0 Source data is 32 bit/pixel ▪ 1 Source data is 24 bit/pixel
<b>pattern</b> <b>&lt;29&gt;</b>	<b>PATTERNing</b> enable: This bit specifies whether patterning is enabled when performing <b>BLIT</b> operations.  ▪ 0 Patterning is disabled . 1 Patterning is enabled  This bit also specifies whether the two banks are to be cleared in parallel when block mode is enabled when <b>fbm = 01XX</b> . Note that when the two banks are cleared in parallel, the fringes aren't processed correctly, and so must be processed separately.  ▪ 0 One bank only . 1 Two banks in parallel
<b>transe</b> <b>&lt;30&gt;</b>	<b>TRANSpa</b> rency Color enabled: This field must be valid for <b>BLITs</b> with color expansion. This bit specifies whether the background color is written.  . 0 Background color is opaque ▪ 1 Background color is transparent
<b>Reserved</b> <b>&lt;31,24,15:8&gt;</b>	Reserved: Writing has no effect.

Memory Address 1C04

Attributes W- F

Reset Value 0000 0000 h

**pwidth**  
<1:0>

Pixel WIDTH: Specifies the pixel width for drawing.

<i>pwidth</i>		
<i>Value</i>	<i>Mnemonic</i>	<i>Mode</i>
<b>00</b>	PW8	8 bits/pixel
01	PW16	16 bits/pixel
10	PW32	32 bits/pixel
11	—	Reserved

**fbc**  
<3:2>

Frame Buffer Configuration: Specifies if the double buffer is used when drawing.

<i>fbc</i>		
<i>Value</i>	<i>Mnemonic</i>	<i>Mode</i>
<b>00</b>	SBUF	Full pixel width
01	—	Reserved
10	DBUFA	Buffer A
11	DBUFB	Buffer B

When the system is in double-buffer mode, and pwidth specifies 8 bits/pixel (4 bits per buffer) or 32 bits/pixel (16 bits per buffer), the plane write mask *must be used* in order to prevent modification of the pixels in the other corresponding buffer. When pwidth specifies 16 bits/pixel, only the targeted buffer will be modified. In this case, the plane write mask *must not be used* with ZI drawing when fbm = 10.

**Reserved**  
<31:4>

Reserved: Writing has no effect.

Memory Address 1 CO8

Attributes W-F

Reset Value FFFF FFFF h

mctlwtst

**mctlwtst**  
**<31:0>**

Memory **ConTroL WaiT SState** register: Specifies the number of wait states added to the memory sequencer. For each part of the memory cycle, a different 2-bit subfield is used. The contents of this register depend on of the type and speed of the RAM, and on the board configuration. Each subfield is defined as follows:

- mctlwtst<x+ 1 :x>
- 00 1 gclk
- 01 2 gclks
- 10 3 gclks
- 11 4 gclks

<i>Description</i>	<i>Mnemonic</i>	<i>Register Field</i>
DEFAULT	DFLT	mctlwtst<1:0>
RAS SETUP	R_SU	mctlwtst<3:2>
RAS HOLD	R_HD	mctlwtst<5:4>
CAS SETUP	C_SU	mctlwtst<7:6>
HOST DELAY	HOST-D	mctlwtst<9:8>
CAS HOLD	C_HD	mctlwtst<11:10>
READ CAS HOLD	RC_HD	mctlwtst<13:12>
HYPER READ CAS HOLD	HRC_HD	mctlwtst<15:14>
Z READ CAS HOLD	ZRC_HD	mctlwtst<17:16>
RAS PRECHARGE	R_PR	mctlwtst<19:18>
ZI RAS HOLD	ZIR_HD	mctlwtst<21:20>
HYPER READ RAS PRECHARGE	HRR_PR	mctlwtst<23:22>
Z RAD HOLD	ZR_HD	mctlwtst<25:24>
SWITCH BUS	SWT_B	mctlwtst<27:26>
WAIT	W_	mctlwtst<29:28>
LAST PIXEL	L P	mctlwtst<31:30>

Programming mctlwtst (80 ns VRAMs):

1. C4001010h
2. C4001110h (one more gclk for BUCOL ILOAD access)

C4001010h is the default value to use, except for BUCOL ILOADs. In the latter case, mctlwtst is programmed to C4001110h prior to the BUCOL ILOAD execution. It's put back to C4001010h when the BUCOL ILOAD execution has finished.

## Destination in

## DST1-0

**Memory Address** 1C10      **Attributes** R- D

**Reset Value** Loaded from vd<63:0>

63	32 31	0
dstil		dsti0

**dsti0**  
**<31:0>**  
**dstil**  
**<63:32>**

DeSTination In register: The dsti0 and dstil fields are used to load configuration data on reset. The destination registers are normally used by the drawing engine. They are readable, however, since their values are initialized from the data bus on reset (breset). Note that the registers must be read before any direct access to the frame buffer or drawing engine operation is performed in order to obtain valid data.

For more information on the definition of each bit on power up, refer to Section 3.6, 'Power Up and Reset'.

Memory Address	1C18	Attributes	W-F	Reset Value	XXXX XXXX h
----------------	------	------------	-----	-------------	-------------

- zcol<3:0>** Z COLor: This field is used by the Depth Mask ALU as the source operand.
- plnzmsk <7:4>** PLaNe Z MaSK: These bits are used to select the plane on the ZTAG RAM.
- zten <8>** Z tag ENable: When 0, ZTAG RAM writes are inhibited; when 1, ZTAG RAM writes are enabled (refer to Section 6.3.3 for more information).
- zcolblk <9>** Z COLor select in BLock mode: This bit is used to load the ZTAG with 0 or 1 when in block mode.
- Reserved <31:10>** Reserved: Writing has no effect.

**Notes:**

Since the ZTAG is used as a tag for the depth buffer, the following values are typically used:

Operation	zcolblk	zcol	plnzmsk
Z drawing	X	0000	1111
Z clear (all)	1	1111	1111
Z clear (partial)	1	pixsla	pixslb
Normal drawing;	X	0000	0000

where ‘pixsla’ and ‘pixslb’ are used to select which pixels in the depth buffer are updated in this group of 16 pixels. A pixel (as shown in the following illustration) is written when both the ‘col’ and the plnzmsk related to it are ‘1’.

Memory Address 1C1C

**plnwrmsk  
<31:0>**

**PLaNe WRite MaSK:** Specifies the plane or planes to be protected during any write operations. During intensity buffer write operations, the contents of this register are transmitted to the VRAMs through the vd<63:0> bus where they are latched on the falling edge of RAS/.

- 0 = Inhibit write
- 1 = Permit write

In 8 and 16 bits/pixel modes, some bits have to be replicated. Refer to Figure 3-8 for the definition of the slice for each mode.

❖ **Note:** When performing a drawing operation with Z when fbm = 10, the plane write mask *must not be used*, since the mask will affect both Z (depth) and I (intensity) plane masking.

Memory Address	Attributes	Reset Value
1 C20	W-F	XXXX XXXX h

**backcol**  
<31:0>

**BACKground COLor:** The backcol field is used by the color expansion module to generate the source pixels when the background is selected. As well, the backcol field is used as the background color for anti-aliased characters.

In 8 and 16 bits/pixel modes, some bits have to be replicated. Refer to Figure 3-10 for the definition of the slice for each mode.

**FCOL**

**Foreground color/Background Z value**

Memory Address	Attributes	Reset Value
1 C24	W-F	XXXX XXXX h

**forcol**  
<31:0>

**FOReground COLor:** The forcol field is used by the color expansion module to generate the source pixels when the foreground is selected. As well, forcol is used as foreground color for anti-aliased characters.

In 8 and 16 bits/pixel modes some bits have to be replicated. Refer to Figure 3-10 for the definition of the slice for each mode.

**backz**  
<15:0>

**BACKground Z value:** The backz field is used with primitives that use the Z buffer. When the ZTAG bit specifies a background depth value, the backz register is selected instead of the destination register to perform the comparison.

## Source register

The XYSTRT register is not a physical register. It is simply an alternative way to load registers AR5, AR6, XDST and YDST.

The XY STRT register is only used for LINE and AUTOLINE. XY STRT does not require initialization for polylines because all the registers affected by XYSTRT are updated to the endpoint of the vector at the end of the AUTOLINE.

When XYSTRT is written, the following registers are affected:

- . X\_START<15:0> --> xdst<15:0>
- X\_START<15:0>-->ar5<17:0> (sign extended)
- . Y\_START<15:0> --> ydst<23:0> (sign extended)
- . 0 --> sellin
- 1 --> newy
- . Y\_START<15:0> --> ar6<17:0> (sign extended)

**x-start  
<15:0>**

X STARTing coordinate: x-start contains the X coordinate of the starting point of the vector. It is a 16-bit signed value in two's complement notation.

**y-start  
<31:16>**

Y STARTing coordinate: y-start contains the Y coordinate of the end point of the vector. This coordinate is always XY (this means that to use the XYSTRT register the linearizer must be used). It is a 16-bit signed value in two's complement notation.

**sdylxl**  
<0>

Sign of Delta Y minus Delta X: This bit is shared with scanleft. It is defined for LINE drawing only and specifies the Major axis. This bit is automatically initialized during AUTOLINE operations.

- 0 Major axis is Y
- . 1 Major axis is X

**scanleft**  
co>

Horizontal SCAN direction LEFT (1) vs RIGHT (0): This bit is shared with sdylxl. It is used for TRAP and BLIT drawing. The scanleft bit is set according to the X scanning direction in a BLT or filled trapezoid.

Normally, this bit is always programmed to zero except for BITBLT when bltmod = BPLAN or BFCOL.

**sdxl**  
<1>

Sign of delta X (line draw or left trapezoid edge): The sdxl bit specifies the X direction for a line draw (opcode = LINE) or the X direction when plotting the left edge in a filled trapezoid draw. This bit is automatically initialized during AUTOLINE operations.

- 0 delta X is positive
- 1 delta X is negative

**sdyl** <2>

Sign of delta Y: The sdyl bit specifies the Y direction of the destination address. This bit is automatically initialized during AUTOLINE operations.

- . 0 delta Y is positive
- . 1 delta Y is negative

**Reserved**

**LEN****Length****Memory Address** 1C5C**Attributes** W-FKD**Reset Value** XXXX XXXX h

**length <15:0>** LENGTH: The length bit is a 16-bit unsigned value.

- . The length field doesn't require initialization for auto-init vectors.
- For a vector draw, length is programmed with the number of pixels to be drawn.
- . For Blits and trapezoid fills, length is programmed with the number of lines to be filled or BLITed.

**Reserved <31:16>** Reserved: Writing has no effect.

**AR0****Multi-purpose address register 0****Memory Address** 1C60**Attributes** W-FKD**Reset Value** XXXX XXXX h

**ar0 <17:0>** Address Register 0: The ar0 field is an 18-bit signed value in two's complement notation.

- For AUTOLINE, this register holds the X end address (see the XYEND register description on page 5-23).
- For LINE, it holds 2 x 'b'.
- . For a filled trapezoid, it holds 'dYI'.
- . For a BLIT, ar0 holds the line end source address 'sea'.

Refer to Table 3-1 for more information.

**Reserved <31:18>** Writing has no effect.

## Multi-purpose address register 1

AR1

<b>Memory Address</b> 1C64	<b>Attributes</b> W-FKD	<b>Reset Value</b> XXXX XXXX h
----------------------------	-------------------------	--------------------------------

### arl <23:0>

Address Register 1: The arl field is a 24-bit signed value in two's complement notation. This register is also loaded when ar3 is accessed.

. For LINE, it holds the error term (initially  $2 \times 'b' - 'a' - [sdy]$ ).

- This register does not need to be loaded for AUTOLINE.

. For a filled trapezoid, it holds the error term in two's complement notation; initially:

$$'errl' = [sdxl] ? 'dXI' + 'dYI' - 1 : -'dXI'$$

- For a BLIT, arl holds the line start source address 'ssa'. Because 'ssa' is also required in ar3 and when writing ar3, arl is loaded, this register doesn't need to be explicitly initialized.

### Reserved <31:24>

Reserved: Writing has no effect.

## Multi-purpose address register 2

AR2

<b>Memory Address</b> 1C68	<b>Attributes</b> W-FKD	<b>Reset Value</b> XXXX XXXX h

**ar4**  
**<17:0>**

Address register 4: The ar4 field is an 18-bit signed value in two’s complement notation.

- For TRAP, it holds the error term. Initially:  

$$‘errr’ = [sdxr] ? ‘dXr’ + ‘dYr’ - 1 : -‘dXr’$$

- . This register is used during AUTOLINE, but it doesn’t need to be initialized.
- . This register is not used for LINE or BLIT operations.

**Reserved**  
**<31:18>**

Reserved: Writing has no effect.

## Multi-purpose address register 5

AR5

Memory Address 1C74

Attributes W-FKD

Reset Value XXXX XXXX h

**ar5**  
**<17:0>**

Address Register 5: The ar5 field is an 18-bit signed value in two's complement notation.

- . At the begining of AUTOLINE, ar5 holds the X start address (see the XYSTRT register on page 5-22). At the end of AUTOLINE the register is loaded with the X end, so it is not necessary to reload the register when drawing a polyline.
- . This register is not used for LINE without Auto initialization.
- . For TRAP, it holds the minor axis increment -ldYrl.
- . In BLIT algorithms, ar5 holds the pitch of the source operand 'sync' (See Table 3-1). A negative pitch value specifies that the source is scanned from bottom to top while a positive pitch value specifies a top to bottom scan.

**Reserved**  
**<31:18>**

Reserved: Writing has no effect.

## Multi-purpose address register 6

AR6

Memory Address 1C78

Attributes W-FKD

Reset Value XXXX XXXX h

**ar6**  
**<17:0>**

Address Register 6: This field is an 18-bit signed value in two's complement notation. It is sign extended to 24 bits before being used by the ALU.

- . At the begining of AUTOLINE, ar6 holds the Y start address (see the XYSTRT register description on page 5-22). During AUTOLINE processing, this register is loaded with the signed Y displacement. At the end of AUTOLINE the register is loaded with the Y end, so it is not necessary to reload the register when drawing a polyline.
- . This register is not used for LINE without Auto initialization.
- . For TRAP, it holds the major axis increment 'dYr'.
  - This register is not used for BLIT operations.

**Reserved**  
**<31:18>**

Reserved: Writing has no effect. These bits return all zeroes when read.

Memory Address 1C8C

Attributes W-FKD

Reset Value XXXX XXXX h

**iy**  
**<12:0>**

Y Increment: This field is a 13-bit unsigned value. The Y increment value is a pixel unit, and it must be a multiple of 32 (the five LSB = 0). This field specifies the increment to be added to or subtracted from ydst between two destination lines. This field is also used as the multiplier factor for linearizing the iy register.

It should be noted that only a few values are supported for linearization. If the pitch selected can't be linearized, the ylin bit should be used to disable the linearization operation. The following table provides the supported pitch for linearization:

<i>Pitch</i>	<i>iy</i>	<i>Pitch</i>	<i>iy</i>
512	000100000000	1152	001001000000
640	000101000000	1280	001010000000
768	000110000000	1536	001100000000
800	000110010000	1600	001100100000
1024	001000000000		

**Reserved**  
**<14:13>**

Reserved: Writing has no effect.

**ylin <15>**

Y LINearization: This bit specifies if the address must be linearized or not.

- 0 Linearize the address
- 1 Don't linearize the address

**Reserved**  
**<31:16>**

Reserved: Writing has no effect.

Memory Address 1C90 Attributes W-FKD

Reset Value XXXXXX 0 XXXXXXXXXXXXXXXXXXXXXXXXXXXX b

**ydst**  
<23:0>

Y DeSTination: The ydst field contains the current Y coordinate of the destination address as a signed value in two’s complement notation. Two formats are supported: linear format and XY format. The current format is selected by ylin.

When XY format is used, ydst represents the Y coordinate of the address. The valid range is -32768 to +32767 (16-bit signed). The XY value is always converted to a linear value before being used.

When linear format is used, ydst must be programmed as follows:

$$ydst \leftarrow (Y \text{ coordinate}) \times \text{PITCH} \gg 5$$

The Y coordinate range is from -32768 to +32767 (16-bit signed) and the pitch range is from 32 to 6144. Pitch is also a multiple of 32.

- Before starting a vector draw, ydst must be loaded with the Y coordinate of the starting point of the vector. This can be done by accessing the XY\_START register. This register does not require initialization for polyline operations.
- Before starting a BLIT, ydst is loaded with the Y coordinate of the starting corner of the destination rectangle.
- For trapezoids, this register must be loaded with the Y coordinate of the first scanned line of the trapezoid.

**newy**  
<24>

NEW Y: The newy field is a 1-bit field which is always set every time the register is written by the processor (bit 24 of the data bus is discarded). This bit is cleared when ydstorg is added to ydst. This bit is used to inhibit the linearization of an address which has already been linearized. This bit is also set when the host accesses the XYSTRT register.

**Reserved**  
<28:25>

Reserved: Writing has no effect.

**sellin**  
<31:29>

SElEcted LINE. The sellin field is used to perform the dithering, patterning, and transparency functions. During linearization, this field is loaded with the three LSB of ydst. If no linearization occurs, then those bits have to be initialized correctly if one of the above-mentioned functions is to be used.

**ydstorg**  
<26:0>

**DeSTination Y ORiGin:** The ydstorg field is a 27-bit unsigned value. It gives an offset value in pixel units, in order to position the first pixel of the first line of the screen. This register is used to initialize the YDST address.

This register must be loaded with a multiple of 32 (the five LSB = 0).

**Reserved**  
<31:27>

Reserved: Writing has no effect.

**YTOP****Clipper Y top boundary**

Memory Address	Attributes	Reset Value
1C98	W-FK	XXXX XXXX h

**cytop**  
<26:0>

**Clipper Y top boundary:** The cytop field contains an unsigned 27-bit value which is interpreted as a positive pixel address and compared with the current ydst. The value of the ydst field must be greater than or equal to cytop to be inside the drawing window.

This register must be programmed with a linearized line number:

$$\text{cytop} = (\text{TOP LINE NUMBER}) \times \text{PITCH} + \text{YDSTORG}$$

This register must be loaded with a multiple of 32 (the five LSB = 0).

Note that since the cytop value is interpreted as positive, any negative ydst value is automatically outside the clipping window. There is no way to disable clipping.

**Reserved**  
<31:27>

srcy lin  
<23:0>

SouRCeLiNear Y coordinate: Represents the linearized Y coordinate when accessing the VRAM window memory region.

$$\text{SrcYLin} = Y \times (\text{byte pitch})$$

$$\text{where byte pitch} = (\# \text{ pixels/line}) \times (\# \text{ bytes/pixel})$$

This register must be loaded with a multiple of 32 (the five LSB = 0). The five LSB of this register are always read as zero.

During VRAM read or write direct access, the address that is used by the VRAM is generated from srcylin and the host address bits <12:2>.

The figure below illustrates how vaddr (the VRAM address) is generated. The 'A' variable represents bits 23:5 of the VRAMPAGE register, 'B' represents host address bits, and 'C' is the result of the addition of A and B, aligned as shown below.

Reserved  
<31:24>

<31:4>

Reserved: Writing has no effect. These bits return all zeroes when read.

<b>Memory Address</b> 1E28 (MEM PCI)	<b>Attributes</b> R/W
<b>Reset Value</b> 0000 0000 0000 0000 0000 0000 0000 0000b	

❖ Note that this register only exists in the PCI configuration.

**Reserved <31:9>** This field is always read as 0000h.

**vgainten <8>** This bit indicates whether or not the VGA interrupt is enabled. As the other internal ATHENA interrupt, VGA interrupt status is available on tirqsts.

- . 0: VGA interrupts are disabled
- 1: VGA interrupts are enabled

**Reserved <7:2>** This field is always read as 0000h.

**eirqsts <1>** Indicates when read as '1' that an external interrupt has occurred. This status is set when an edge is detected on the eirqN pin.

A read to this bit accesses its value normally. A write, however, is slightly different in that the bit can be reset, but not set. This bit is reset whenever the register is written, and the data in the corresponding bit location is 1.

**tirqsts <0>** Status of the tirq pin. When 0, indicates that the source of the interrupt on INTA is from the ATHENA chip.

<b>Reset</b>	<b>RST</b>
<b>Memory Address</b> 1E40	<b>Attributes</b> R/W
<b>Reset value</b> 0000 000Q h	

**softreset <0>** SOFT RESET: When set to '1', resets all host register bits, except those which are hard reset only. The soft reset signal is synchronous on gclk, and takes place at the end of the write cycle. On the next read, all concerned bits will be reset.

A '0' must be programmed to remove the softreset. Writes to this field are glitch-free.

**Reserved <31:1>** Reserved: Writing has no effect. These bits return all zeroes when read.

Memory Address 1E44 (MEM)	Attributes	R/W - STATIC	Reset Value

Reset value A268 1702h  
Reset Used X**chiprev**  
<6:0>

CHIP REVISION code: Read value is 01h. This value will change if there are any chip revisions.

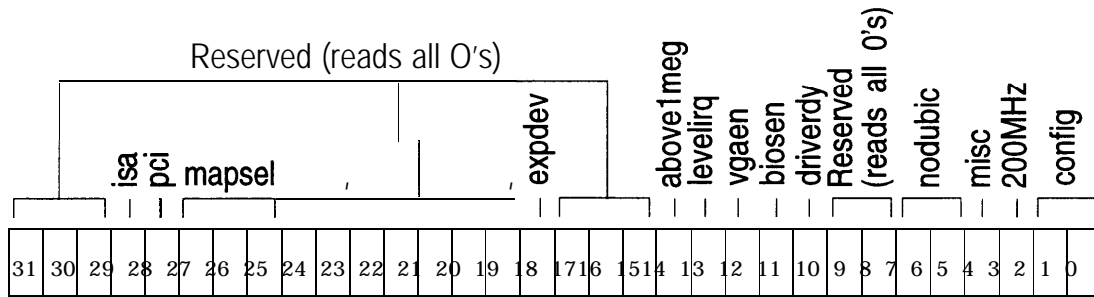

**athena id**  
<31:7>

ATHENA IDENTIFICATION: This field provides a fixed non-zero identification. It may be used to help locate the MGA when the value of mapsel is unknown to the software.

Since MGA ATHENA is part of the same family as the MGA TITAN chip (a precursor of ATHENA), and in order to make software programming easier, the same ID is used for all MGA chips. ATHENA can be differentiated from the TITAN and ATLAS chips by the *chip revision number*. The data is the 5-bit ASCII code for the name "TITAN".

Memory Address 1E50 (MEM) Attributes R/W

Reset Value 000H HHHH 0000 0000 000H 0HHH 000H 00HH b

❖ Note: In order to respect the Tr24 timing, software must wait after accessing this register. Only byte accesses should be made to this register.

**config  
<1:0>  
R/W**

CONFIGuration bits: Sampled on reset, this field assumes the external strapping configuration value. The reset value can be overwritten. Writes to this field are glitch-free Note that only byte access (byte 0) is permitted for modification of the config bits.

Bit 1 is used as the narrow decode configuration bit. When '1', mcs16N is a decode based on ISA bus addresses LA<23:17>, which represents a 128K range. When '1', mcs 16N will also depend on SA<16:14>, which represents the narrow decode of the 16K MGA space and 32K ROM space. No mcs16N sampling is supported.

The VGA frame buffer and IO port are always 8-bit devices.

The configuration determines whether ATHENA's resources are 8-16- or 32-bit devices, according to the tables which follow.

<i>biosen</i>	<i>config&lt;1:0&gt;</i>	<i>BIOS</i>	<i>mcs16N</i>	<i>ex32N</i>
0	xx	No decode	1	1
1	00	8	1	1
	01	16	0	1
	10	Reserved	1	1
	11	16 narrow	0	1

<i>isa</i>	<i>mapsel</i>	<i>vgaen</i>	<i>config&lt;1:0&gt;</i>	<i>MGA</i>	<i>mcs16N</i>	<i>ex32N</i>
0	000	X	x x	No decode	1	1
	001	0	x x	32 narrow	1	0
	001	1	x x	8	1	1
	010-111	x	XX	32 narrow	1	0

X = 'don't care'

● 3 Note: Only byte accesses (byte0) are permitted for modification of these bits. In the PCI configuration, these bits must be set to '00'.

Refer to Section 3.6.3 to determine the reset value of config<1:0>.

**200MHz<2>** 200 MHz function. A strap exists on the RESET configuration bus to identify boards that are capable of functioning with a pixel clock of up to 200 MHz. This strap is read from VD<48> at reset. This bit must be read by software, inverted, then loaded into CONFIG<2>. It is interpreted as follows:

<i>200MHz</i>	<i>Meaning</i>
1	Board supports 200 MHz operation
0	Board only supports regular (135 MHz-170 MHz) operation

**misc<3>** MISCellaneous bit: Reserved for future use. This field has no definition. This is a multi-purpose software bit.

**R/W**

Refer to Section 3.6.3 to determine the reset value of this bit.

**nodubic<5:4>** These bits indicate the presence of a DUBIC chip and whether or not external multiplexers are used. CONFIG<4> is sampled from VD<50> and inverted on reset. CONFIG<5> is cleared to zero on reset, and must be read from VD<49> (DST1<17>), inverted, then loaded into this bit. Writes to this bit are glitch-free.

**R/W**

<i>nodubic</i>	<i>Meaning</i>
00	DUBIC present (TITAN-compatible)
01	No DUBIC present. ATHENA controls VRAM and RAMDAC directly (external multiplexers are required on VRAM serial outputs).
10	Reserved
11	No DUBIC present. ATHENA controls VRAM and RAMDAC directly (external multiplexers are not used).

**Reserved <7:6>**

Reserved: Writing has no effect. These bits return all zeroes when read.

**driverdy <8> RO**

DRIVE channel ReaDY: Sampled on reset, this bit assumes the external strapping configuration value. The reset value can't be overwritten. All interrupts should be disabled when writing to this bit.

This field determines how the CHRDY/ signal is generated:

<i>Value</i>	<i>Meaning</i>
0	The CHRDY signal output is tri-stateable, and the CHRDYEN/ enable signal is a delayed version of CHRDY.
1	The CHRDY signal is always driven by ATHENA, and an external tri-state buffer is required.

In the PCI configuration, this bit must be set to '1'. Refer to Section 3.6.3 to determine the reset value of this bit.

**biosen**  
**<9> R/W**

BIOS ENable: Set to '1' on reset if vgaen is sampled active ('1'). The reset value can be overwritten. When set to '1', the VGA BIOS is enabled.

Note that the BIOS can be enabled separately from the VGA I/O and the frame buffer. This way, the board that boots as the VGA device can always keep its BIOS active if desired. Also, there can always be a BIOS active, even when there's no active VGA (except at boot-up). All interrupts should be disabled when writing this bit.

**vgaen**  
**<10> R/W**

VGA ENable: Sampled on reset, this bit assumes the external strapping configuration value. The reset value can be overwritten. All interrupts should be disabled when writing this bit. Writes to this field are glitch-free.

Value	Meaning
0	VGA is disabled
1	VGA is enabled

Refer to Section 3.6.3 to determine the reset value of this bit.

**levelirq**  
**<11> R/W**

LEVEL Interrupt Request: This bit is used to select between a positive edge triggered or a level-sensitive interrupt.

. When '0' (hard reset value), ATHENA produces a positive edge interrupt.

. When set to '1', ATHENA produces a negative level interrupt.

See Section 3.2.6 for more details about ATHENA's interrupts.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value. All interrupts should be disabled when writing this bit.*

**abovemeg**  
**<12> R/(W)**

Mapped ABOVE 1 MEG: Sampled on reset, this bit assumes the external strapping configuration value.

For test purposes, this bit can be modified by a write. To do this, the robitwren bit from the TEST register must be set to '1'. All interrupts should be disabled when writing this bit. Writes to this field are glitch-free.

Refer to Section 3.6.3 to determine the reset value of this bit.

. When above 1 meg is active (1):

□ decodeN<1> may be used to decode any address bits down to bit 20. It should be active when la<31:20> (or just la<23:20> on an ISA machine) decodes the MGA range.

□ decodeN<0> should be tied to '0' in an ISA machine. In other systems, it should be active when lac3 1:24> = 00h is decoded.

- . When above 1 meg is inactive (0):
  - decodeN<1> and decodeN<0> should be tied to '0'.

In the PCI configuration, this bit must be set to '0'.

**Reserved  
<15:13>**

Reserved: Writing has no effect. These bits return all zeroes when read.

**expdev  
<16> R/W**

EXPansion DEvice: This bit affects EXPSL/. On power up, software must read the external strapping value in the destination register, and set this bit properly.

*This field is considered semi-static. It should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value. This field indicates the availability of external expansion devices:*

Value	Meaning
0	No expansion device is available
1	Expansion device is accessible

Refer to Section 3.6.3 to determine the reset value of this bit.

**Reserved  
<23:17>**

Reserved: Writing has no effect. These bits return all zeroes when read.

**mapsel  
<26:24>  
R/(W)**

Sampled on reset, this field assumes the external strapping configuration value. The mapsel field determines the base of the MGA address map. For more details, see Chapter 4. Writes to this field are glitch-free.

For test purposes, mapsel<2:0> can be modified by a write. To do this, the robitwren bit from the TEST register must be set to '1'.

Refer to Section 3.6.3 to determine the reset value of these bits.

- . MAPSEL1 should only be used if you boot in VGA mode
- . MAPSELO can be used if you boot in VGA mode for system debugging. In this mode, MGA is not mapped. But you may still boot and configure your system using the VGA display.

In the PCI configuration, these bits must be set to '010'.

**pci<27>  
R/(W)**

PCI Bus Identification: Sampled on reset, this bit assumes the external strapping configuration value. It is used in conjunction with the isa field to determine the current host interface type.

To write this bit, the robitwren bit in the TEST register must be set to '1'. Writes to this field are glitch-free.

Refer to Section 3.6.3 to determine the reset value of this bit.

**isa<28>  
R/(W)**

ISA Bus Identification: Sampled on reset, this bit assumes the external strapping configuration value. This bit is used in conjunction with the pci field to determine the current host interface type.

To write this bit, the robotwren bit in the TEST register must be set to '1'. Writes to this field are glitch-free.

<i>isa</i>	<i>pci</i>	<i>Bus Type</i>
<b>0</b>	<b>0</b>	Reserved
0	1	PCI Bus
1	0	ISA Bus
1	1	Reserved

Refer to Section 3.6.3 to determine the reset value of this bit.

**Reserved  
<31:29>**

Reserved: Writing has no effect. These bits return all zeroes when read.

Memory Address 1E54      Attributes R/W  
 Reset value 000000000000000000 H000 0000 0000 b

❖ Note: In order to respect the Tr24 timing, software must wait after accessing this register. Only byte accesses should be made to this register.

**pseudodma**  
 <0> R/W

PSEUDO DMA: When set to '1', the VRAM window becomes a DMA access port. This will allow movestring access to the Bus FIFO. In order to start a new Pseudo DMA sequence, this bit and dmaact must be '0', dmamod must be initialized, then, in a separate access, this bit should be set to '1'.

Writes to this field are glitch-free.

**dmaact**  
 cl> R/W

DMA ACTIVE: When set to '1', indicates the beginning of a DMA transfer. This bit is reset to '0' automatically, when the DMA terminal count (TC) is sampled active.

Once set to '1', only a DMA terminal count, a hard reset, or a soft reset will return dmaact to '0'. Writing a '0' to this bit will have no effect. In order to start a new DMA sequence, this bit and pseudodma must be '0', dmamod must be initialized, then, in a separate access, this bit should be set to '1'.

Writes to this field are glitch-free.

**dmamod**  
 <3:2> R/W

DMA MODE: There are four DMA or Pseudo DMA transfer modes on the ATHENA, selected through the DmaMod bits. These bits must be programmed before starting DMA or Pseudo DMA transfer. The dmaact and pseudodma bits must be '0' before modifying these bits.

<i>dmaMod&lt;1:0&gt;</i>	<i>DMA</i>	<i>PSEUDO DMA</i>	<i>DMA transfer mode description</i>
00	Yes	Yes	DMA General Purpose Write
01	Yes	Yes	DMA BLIT Write
10	Yes	Yes	DMA Vector Write
11		Yes	DMA BLIT Read (IDUMP)

Writes to this field are glitch-free.

**nowait**  
 <4> R/W

NO WAIT: This bit is used to select between: always adding waits (0); and only adding waits when necessary (1).

When '0' (the reset value), ATHENA will automatically generate wait states on all accesses to the board. Normally, this bit should be set to '1' by software so as not to unnecessarily deteriorate the performance.

This feature may be used to help prevent problems in AT clones and compatibles that have bus speeds above 8.33 Mhz. Software should provide a configuration mechanism so that the bit may remain inactive in problem systems. Writes to this field are glitch-free.

**Automatic wait mechanism**

Some devices decoded by ATHENA do not require any additional wait states. An automatic wait mechanism has been implemented in ATHENA for the case of devices that may not follow the speed of some rapid systems.

When the automatic wait is required (**nowait** = 'O'), the bus will be put into wait for an equivalent time of 100 ns to 125 ns when an access to some devices is decoded.

These devices are:

- Drawing registers (read and write to offset range 1C00h-1DFFh)
- . Host registers (read and write to offset range 1E00h-1EFFh)
- . Pseudo-DMA window (read and write to offset range 0000h -1BFFh, with vgaen = 0 and pseudodma = 1)
- VRAM direct write (write to offset range 0000h -1BFFh, with vgaen = 0 and pseudodma = 0)

Note: Some devices do not use automatic wait because they're already using wait states in normal operation. These devices are:

- BIOS ROM
- VRAM direct read
- VGA frame buffer read and write
- . External devices read and write, I/O or memory
- VGA register in the Power Graphic mode memory space (read and write to offset range 1F00h -1FFFh, with vgaen = 0)

**Reserved**  
**<7:5>**

Reserved: Writing has no effect. These bits return all zeroes when read.

**mouseen**  
**<8> R/W**

MOUSE ENable: When set to '1', this bit enables mouse decode for the DUBIC chip. The mousemap field should be programmed at the same time as this field, so the appropriate map will be selected when the decode is enabled.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value.*

**mousemap**  
**<9> R/W**

MOUSE MAP: When mouseen is active ('1') and mousemap=0, the mouse port is decoded in I/O space at 23Ch-23Fh.

When mouseen is active and mousemap=1, the mouse port is decoded in I/O space at 238h-23Bh.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value.*

**Reserved**  
**<10>**

Reserved: Writing has no effect. These bits return all zeroes when read.

**vgabank0**  
**<11> R/W**

VGA BANK 0: Sampled on hard reset, this bit assumes the external strapping configuration value. During hard reset, the control signal derived from this register bit is forced to guarantee the reset path to the VGA straps which come from the vd bus.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value.* When fbm = 3, vbank0 should be set to 0 (Bank 2).

Value	Meaning
0	Boot in Bank 2
1	Boot in Bank 0

Refer to Section 3.6.3 to determine the reset value of this bit.

**Reserved**  
**<15:12>**

Reserved: Writing has no effect. These bits return all zeroes when read.

**rfhcnt**  
**<19:16>**  
**R/W**

ReFresHCouNter: This field defines the rate of VRAM/DRAM refresh requests.

Program (round the fraction to the nearest integer):

$$\text{rfhcnt} = \text{RAM refresh period } \mu\text{S} \times \text{clock-frequency Mhz} / 64.$$

For a typical 40Mhz system, a value of 9 is programmed in rfhcnt.

$$\text{rfhcnt} = 15.625 \mu\text{S} \times 40 \text{ Mhz} / 64.$$

During the reset period, the refresh request is continuously forced to its inactive state so that no VRAM activities will occur. By maintaining the reset low for 200  $\mu\text{S}$ , a proper VRAM initialisation will occur (valid for power up or after a VRAM error).

Writes to this field are glitch-free.

**fbm**  
**<23:20>**  
**R/W**

Frame Buffer Mode: This field specifies the mode used to draw in the frame buffer. The modes are used to generate all xRAM control strobes and addresses. For more information about frame buffer mode, refer to Section 3.2.1.

Writes to this field are glitch-free.

**hyperpg**  
**<25:24>**  
**R/W**

HYPER PaGe: On power up, software must read the external strapping value in the destination register (DST1), and set this bit accordingly.

<i>hyperpg&lt;1:0&gt;</i>		
<i>dmaMod&lt;1:0&gt;</i>	<i>Mnemonic</i>	<i>Operation</i>
00	NOHYPER	NO HYPER-PAGE (default)
01	SELHYPER	HYPER-PAGE on 256Kx8 SECTIONS (Bank = 2, 3, 4)
10	ALLHYPER	ALL HYPER-PAGE
11	—	Reserved

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value. Writing this field may cause spurious errors. It should only be written during the product configuration process.*

These bits are read from VD<52:51> during reset. Software must read these bits from DST1<20:19> and load them here.

**tram <26>  
R/W**

Type of VRAM: The tram field is used by the CRTC for data transfer request generation. Specifies the type of 256K×? VRAM used for Banks 2, 3, and 4 (note that all banks should have the same type of VRAM). On power up, software must read the external strapping value in the destination registers (DST0, DST1), and set this bit accordingly.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value. Writing this field may cause spurious errors. It should only be written during the product configuration process.*

Value	Meaning
0	256K x 16 (SAM = 256)
1	256K × 4 or 256K × 8 (SAM = 512)

Read from VD<54> during reset. Software must read this bit from DST1<22>, invert it, then load it here.

**block8/<27>**

This field indicates VRAM support for 8-bit block transfers. The value is read from VD<19> at reset. Software must read this bit, invert it, then store it in OPMODE<27>. The strapping values are as follows:

Value	Meaning
0	4-bit block mode is supported
1	8-bit block mode is supported

**Reserved  
<31:28>**

Reserved: Writing has no effect. These bits return all zeroes when read.

Memory Address 1E5C (MEM) Attributes R/W - STATIC

Reset Value 0000 0000 0000 0000 0000 0000 0000 0000b

**crtcbpp** <1:0> CRTC Bits Per Pixel: Specifies the number of bits per pixel for the video. Writes to this field are glitch-free.

<i>crtcbpp</i>	<i>Number of bits</i>
00	8
01	16
10	32
11	Reserved

**alw** <2> Automatic Line Wrap: Specifies that the video is in automatic line wrap. If set to 0, the video is in non-automatic line wrap. If set to 1, the video is in automatic line wrap. Writes to this field are glitch-free.

**interlace** <4:3> INTERLACE: Indicates interlace mode and pitch. Writes to this field are glitch-free.

<i>interlace</i> <1:0>	<i>Mode</i>
00	Non interlaced
01	Interlace : pitch = 768 (768 and 640)
10	Interlace : pitch = 1024 (800 and 1024)
11	Interlace : pitch = 1280 (1280)

**videodelay** c 10,9,5> VIDEO DELAY Specifies the delay in the dtrequest module between the CRTC signals and the delayed signals sent to the VCTL. The delay must respect three constraints which are described at the end of Section 3.2.5.5. Writes to this field are glitch-free.

<i>videodelay</i> <2:0>	<i>Delay</i>
000	5 vidclk
001	11 vidclk
010	24 vidclk
011	28 vidclk
100	3 vidclk
101	4 vidclk
11x	Reserved

**hrsten <6>** HoRizontal video ReSeT ENable: When set to 1, the horizontal counter of the CRTC can be reset by the VIDRST pin.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value.*

**vrsten <7>** Vertical video ReSeT ENable: When set to 1, the vertical counter of the CRTC can be reset by the VIDRST pin.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value.*

**vesafeat <8>** Activates the extra memory page select bit. Used in VGA mode by the VESA driver to reduce the first memory access window from 64K to 32K.

*This field should be written to only when necessary. When written, it may glitch or pass through an intermediate value, even when rewriting the same value.*

**vscale <17:16>** Video clock pre-SCALing:

These bits are used to specify a pre-scaling factor to the clock that is sent to the CRTC. Writes to this field are glitch-free.

<i>nodubic</i>	<i>vgaen</i>	<i>vscale</i>	<i>Clock divide ration</i>
0	X	XX	1 (bypass)
1	0	00	1 (bypass)
		01	2
		10	4
		11	8
	1	XX	1 (bypass)

**syncdel <19:18>** SYNC DELay: These bits specify the delay that is to be added to the horizontal and vertical sync. The syncdel field has no effect when a DUBIC chip is present, since HSYNC/ and VSYNC/ are not generated by ATHENA. Writes to this field are glitch-free.

<i>vgaen</i>	<i>syncdel</i>	<i>Delay added to HSYNC. and VSYNC/</i>
0	X	1 (bypass)
1	0	1 (bypass)
		2
		4
		8
	1	1 (bypass)

**Reserved <31:20, 15:11>** Reserved: Writing has no effect. These bits return all zeroes when read.

## 5.3 VGA Mode Register Descriptions

### CRTC Address (CRT Controller Register)

**Memory Address** Mono 1FB4 Color 1FD4      **I/O Address** Mono 3B4 Color 3D4

CRTC register index address 7:0

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

**D7-D0**      CRTC Register Index Address  
 These bits select which CRTC register is to be accessed.

### Horizontal Total (CRT Controller Registers)

**Memory Address** Mono 1FB5 Color 1FD5      **I/O Address** Mono 3B5 Color 3D5      **Index** 00

Horizontal total 7:0

7	6	5	4	3	2		10
---	---	---	---	---	---	--	----

**D7-D0**      Horizontal Total  
 These bits define the total number of characters, minus five, in the horizontal scan interval including retrace time. The horizontal period is  $T_H = (R0+5) \times T_C$ ; where R0 is the contents of this register, and  $T_C$  is the period of the input character clock.

### Horizontal Display Enable End (CRT Controller Registers)

**Memory Address** Mono 1FB5 Color 1FD5      **I/O Address** Mono 3B5 Color 3D5      **Index** 01

Horizontal displayed characters 7:0

7	6	5	4	3	2		10
---	---	---	---	---	---	--	----

**D7-D0**      Horizontal Displayed Characters  
 These bits define the length of the horizontal display period. This period is equal to  $(R1+1) \times T_C$ ; where R1 is the contents of this register,  $T_C$  is the period of the input character clock, and providing R1 is less than R0.

Memory Address Mono 1FB5 Color 1FD5 I/O Address Mono 3B5 Color 3D5 Index 0 2

Horizontal blank start pos. 7:0

D7-D0

Horizontal Blank Start Position

The value of this register determines when the horizontal component of the blanking signal becomes active. This component goes high at time (R2+1) x TC after the start of a horizontal cycle; where R2 is the contents of this register, TC is the period of the input character clock, and providing R2 is less than RO.

Memory Address Mono 1FB5 Color 1FD5 I/O Address Mono 3B5 Color 3D5 Index 0 3

D6-D5

Horizontal Skew Bits 1 And 0

These bits determine the skew of the display enable signal as follows:

D6	D5	Disable Enable Skew
0	0	Display enable is not delayed
0	1	Display enable delayed by one character clock
1	0	Display enable delayed by two character clocks
1	1	Display enable delayed by three character clocks

D4-D0

Horizontal Blank End Position Bits 4 To 0

These five bits are the least significant bits of a six-bit total which determines the length of the active horizontal blanking signal. The sixth bit is located at D7 of the horizontal retrace end (Index 05h) register. Horizontal blank end occurs at (using 8-bit math) R2+{ [(Horizontal blank end value AND 3Fh) - (R2 AND 3Fh)] AND 7Fh}.

**Horizontal Retrace Start**

(CRT Controller Registers)

**Memory Address** Mono 1FB5 Color 1FD5      **I/O Address** Mono 3B5 Color 3D5      **Index** 04

Horizontal retrace start pos.

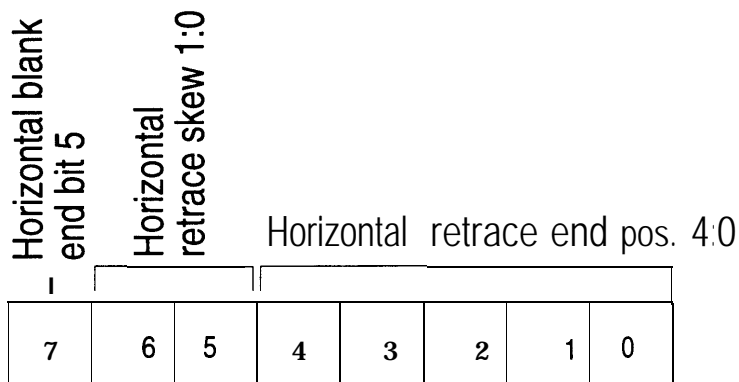

7	6	5	4	3	2	1		0
---	---	---	---	---	---	---	--	---

**D7-D0** Horizontal Retrace Start Position Bits  
The value of these bits determines when the horizontal retrace will start.

**Horizontal Retrace End**

(CRT Controller Registers)

**Memory Address** Mono 1FB5 Color 1FD5      **I/O Address** Mono 3B5 Color 3D5      **Index** 05

**D7** Horizontal Blank End Position Bit 5  
This is the horizontal blank end position MSB. The first five bits are in the horizontal blanking end register (Index 03h).

**D6-D5** Horizontal Retrace Skew Bits 1 And 0  
These bits determine the skew of the horizontal retrace signal as follows:

D6	D5	Horizontal Retrace Skew
0	0	Horizontal retrace is not delayed
0	1	Horizontal retrace delayed by one character clock
1	0	Horizontal retrace delayed by two character clocks
1	1	Horizontal retrace delayed by three character clocks

**D4-D0** Horizontal Retrace End Position Bits 4 To 0  
These bits determine the length of the active horizontal retrace signal. The horizontal retrace end position occurs at (using 8-bit math)  $R4 + \{[(R5 \text{ AND } 1Fh) - (R4 \text{ AND } 1Fh)] \text{ AND } 3Fh\}$

**(CRT Controller Registers)****Vertical Total**

Memory Address	Mono 1FB5 Color 1FD5	I/O Address	Mono 3B5 Color 3D5	Index	06
----------------	----------------------	-------------	--------------------	-------	----

Vertical total 7:0

**D7-D0**

Vertical Total Bits 7 To 0

These are the low-order eight-bits of the ten-bit vertical total. Bits eight and nine are located in the overflow register (Index 07h). Vertical total = Vertical total value+2.

**(CRT Controller Registers)****Overflow**

Memory Address	Mono 1FB5 Color 1FD5	I/O Address	Mono 3B5 Color 3D5	Index	07
----------------	----------------------	-------------	--------------------	-------	----

**D7** Vertical Retrace Start Bit 9: This is bit nine, the MSB of the vertical retrace start register (Index 10h). This bit is reserved in EGA mode.

**D6** Vertical Display End Bit 9: This is bit nine, the MSB of the vertical display enable end register (Index 12h). This bit is reserved in EGA mode.

**D5** Vertical Total Bit 9: This is bit nine, the MSB of the vertical total register (Index 06h). This bit is reserved in EGA mode.

**D4** Line Compare Bit 8: This is bit eight of the line compare register (Index 18h).

**D3** Vertical Blanking Start Bit 8: This is bit eight of the vertical blanking start register (Index 15h).

**D2** Vertical Retrace Start Bit 8: This is bit eight of the vertical retrace start register (Index 10h).

**D1** Vertical Display End Bit 8: This is bit eight of the vertical display enable end register (Index 12h).

**D0** Vertical Total Bit 8: This is bit eight of the vertical total register (Index 06h).

**Preset Row Scan**

**(CRT Controller Registers)**

Memory Address	Mono 1FB5 Color 1FD5	I/O Address	Mono 3B5 Color 3D5	Index	0 8
----------------	----------------------	-------------	--------------------	-------	-----

- D6-D5** Byte Pan Bits 1 And 0  
These bits control the byte panning in modes programmed as multiple shift modes.
- D4-D0** Preset Row Scan Bits 4 To 0  
The value of these bits is the first row value at the start of a vertical period.

**Maximum Scan Line**

**(CRT Controller Registers)**

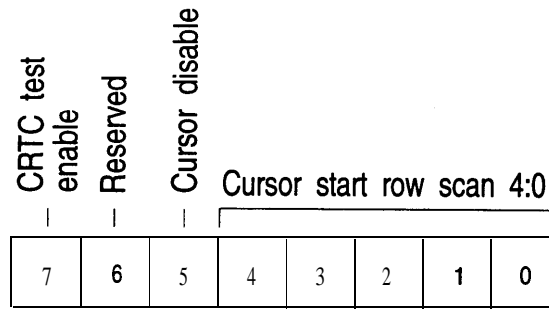

Memory Address	Mono 1FB5 Color 1FD5	I/O Address	Mono 3B5 Color 3D5	Index	09
----------------	----------------------	-------------	--------------------	-------	----

- D7** Line Doubling Enable: This bit is reserved in EGA mode.
  - 0: Disables double scan.
  - 1: Enables double scan.
- D6** Line Compare Bit 9  
This is bit nine, the MSB of the line compare register (Index 18h). This bit is reserved in EGA mode.
- D5** Vertical Blanking Start Bit 9  
This is bit nine, the MSB of the vertical blanking start register (Index 15h). This bit is reserved in EGA mode.
- D4-D0** Maximum Scan Line Bits 4 To 0  
These bits specify the number of scan lines in a character row.

**(CRT Controller Registers)****Cursor Start**

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	O A
----------------	-----------	------------	-------------	----------	-----------	-------	-----

**D7** CRTC Test Enable

- 0: Disables the CRT test circuitry.
- 1: Enables the CRT test circuitry if bit D7 of the extended function register, 3DFh Index 01, is also 1.

**D5** Cursor Disable. This bit is reserved in EGA mode.

- 0: Turns the cursor on.
- 1: Turns the cursor off.

**D4-D0** Cursor Start Row Scan Bits 4 To 0

These bits specify the row scan of a character line where the cursor is to begin.

**(CRT Controller Registers)****Cursor End**

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	O B
----------------	-----------	------------	-------------	----------	-----------	-------	-----

**D6-D5** Cursor Skew Bits 1 And 0

These bits determine the skew of the cursor signal as follows:

D6	D5	Cursor Skew
0	0	Cursor signal is not delayed
0	1	Cursor signal delayed by one character clock
1	0	Cursor signal delayed by two character clocks
1	1	Cursor signal delayed by three character clocks

**D4-D0** Cursor End Row Scan Bits 4 To 0

These bits specify the row scan of a character line where the cursor is to end.

**Start Address High****(CRT Controller Registers)**

Vertical retrace start pos. 7:0

7	6	5	4	3	2		10

**D7-D0**

Vertical Retrace Start Position Bits 7 To 0

These are the eight LSB's of the vertical retrace start position, and is programmed in horizontal scan lines. Bits eight and nine are in the overflow register (Index 07h).

## Vertical Retrace End

(CRT Controller Registers)

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	11
----------------	-----------	------------	-------------	----------	-----------	-------	----

- D7** Register 7-0 Protect. This bit is reserved in EGA mode.  
 . 0: Enables the writing of data to CRTC registers 7 To 0.  
 . 1: Disables the writing of data to CRTC registers 7 To 0.
- D6** Select 5 Refresh Cycles. This bit is reserved in EGA mode.  
 ■ 0: Allows three dynamic RAM refresh cycles per horizontal line.  
 ■ 1: Allows five dynamic RAM refresh cycles to be generated in every horizontal line.
- D5** Enable Vertical Interrupt  
 D5=0 enables the vertical retrace interrupt.
- D4** Clear Vertical Interrupt  
 D4=0 clears the vertical retrace interrupt. After being cleared this bit must be set to 1 so that interrupts are not held inactive.
- D3-D0** Vertical Retrace End Position Bits 3 To 0  
 These bits determine the length of the vertical retrace signal. Since this value is only four bits in length, The maximum length of the vertical retrace signal is 15 clock periods.

## Vertical Display Enable End

(CRT Controller Registers)

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	12
----------------	-----------	------------	-------------	----------	-----------	-------	----

- D7-D0** Vertical Displayed Lines Bits 7 To 0  
 These are the least significant eight bits of the ten-bit value which defines the vertical display enable end position. The value of these ten bits is the total number of lines to be displayed minus one.

**(CRT Controller Registers)**

**Offset**

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	13
----------------	-----------	------------	-------------	----------	-----------	-------	----

Line address offset 7:0

**D7-D0**

Line Address Offset Double Words

These bits are the value used to offset the memory address counter to the beginning of the next displayed character line. This value is the number of double words (or single words) in one character line.

**(CRT Controller Registers)**

**Underline Location**

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	14
----------------	-----------	------------	-------------	----------	-----------	-------	----

**D6**

Double Word Select. This bit is reserved in EGA mode.

- . 0: Causes the memory addresses to be single word addresses.
- 1: Causes the memory addresses to be double word addresses.

**D5**

Count By four. This bit is reserved in EGA mode.

- . 0: Causes the memory address counter to be clocked with the character clock.
- . 1: Causes the memory address counter to be clocked with the character clock divided by four. If the count by two bit (Index 17h bit D3) is set to 1, then this bit has no effect.

**D4-D0**

Underline Row Scan Bits 4 To 0

These bits specify the horizontal row scan of a character row on which an underline occurs.

**Vertical Blanking Start****(CRT Controller Registers)**

Memory Address	Mono 1FB5 Color 1FD5	I/O Address	Mono 3B5 Color 3D5	Index	15
----------------	----------------------	-------------	--------------------	-------	----

Vertical blank start pos. 7:0

**D7-D0**

Vertical Blanking Start Position Bits 7 To 0

These are the least significant eight bits of the ten-bit start vertical blanking value. Bits eight and nine are found in the overflow register (Index 07h) and the maximum scan line register (Index 09h). The value of these ten bits is one less than the horizontal scan line count at which the vertical blanking signal becomes active.

**Vertical Blanking End****(CRT Controller Registers)**

Memory Address	Mono 1FB5 Color 1FD5	I/O Address	Mono 3B5 Color 3D5	Index	16
----------------	----------------------	-------------	--------------------	-------	----

Vertical blanking end position 7: 0

**D7-D0**

Vertical Blanking End Position Bits 7 To 0

The value of these bits specify the horizontal scan count when the vertical blanking signal becomes inactive. This value is in horizontal scan lines.

Memory Address	Mono 1FB5	Color 1FD5	I/O Address	Mono 3B5	Color 3D5	Index	17
----------------	-----------	------------	-------------	----------	-----------	-------	----

**D7** CRTC Reset

- 0: Clears both the horizontal and vertical retrace.
- . 1: Enables both the horizontal and vertical retrace.

**D6** Byte/Word Mode Select

- . 0: Selects word mode. The memory address counter bits are shifted left before being applied to the video memory. Address bit 0 is replaced with either bit 15 or bit 13 of the memory address counter, as selected by the MA 15/MA 13 select bit
- . 1: Selects the byte mode. The memory address counter bits are applied directly to the video memory.

**D5** MA 15/MA 13 Select

- . 0: Selects memory address counter bit 13 to be used as memory address bit 0 in word mode. In byte mode, memory address counter bit 0 is used for memory address bit 0.
- . 1: Selects memory address counter bit 15 to be used as memory address bit 0 in word mode. In byte mode, memory address counter bit 0 is used for memory address bit 0.

**D3** Count By Two

- . 0: Causes the memory address counter to be clocked by the character clock.
- 1: Causes the memory address counter to be clocked by every second character clock.

**D2** Horizontal Retrace Divide Select

- 0: Causes the vertical timing counter to be clocked on every horizontal retrace. The maximum number of horizontal scan lines is 1024.
- . 1: Causes the vertical timing counter to be clocked by every second horizontal retrace. The maximum number of horizontal scan lines is 2048.

- D1** MA 14/Row Scan Select  
 This bit is used to select the internal signal used for memory address 14.
- 0: Causes the row scan counter bit 1 to be used as memory address bit 14 during CRTC reads from display memory.
  - 1: Causes memory address bit 14 to be used as memory address bit 14 during CRTC reads from display memory.
- D0** Compatability Mode Select  
 This bit is used for compatibility with IBM CGA.
- 0: Causes the row scan address bit 0 to be used as memory address bit 13 during CRTC reads from display memory.
  - 1: Causes memory address counter bit 13 to be used as memory address bit 13 during CRTC reads from display memory.

**D1**

Enable Page 1

- . 0: Prevents D7 of the mode control register (3B8h) from being set.
- 1: Allows D7 of 3B8h to be set. The logical AND of this bit and data bus D7 is applied to the bit 7 latch of the mode control port.

D1=0 causes the display memory to appear in the B0000-B7FFFh CPU address range. In text mode, the memory is actually only 4K in size and is repeated (B 1000-B 1FFFh, B2000-B2FFFh, etc. are the same memory as B0000-B0FFFh). D1=1 allows 64K of unique memory to be accessed in the B0000-BFFFFh range.

When in graphics mode, 64K of unique memory is always available. The CPU can access the upper 32K (B8000-BFFFFh) only when D 1= 1.

**D0**

Enable Graphics Mode

- 0: Prevents D1 of 3B8h from being set.
- . 1: Allows D 1 of the mode control register (3B8h) to be set.

The logical AND of this bit and data bus D1 is applied to the bit 1 latch of the mode control port.

**(Attributes Controller Registers)**

**Address**

**Memory Address** 1FC0

**I/O Address** 3C0

A read from port 3BA/3DAh resets this port to the attributes address register. The first read or write to this register after a 3BA/3DAh reset accesses the attributes index, the next read or write accesses the palette. Subsequent reads or writes to this register toggle between index and palette.

**D5**

Palette Enable

- 0: Enables the loading of the palette registers. The display is forced to the overscan color.
- 1: Enables the application of video pixel data to the color palette address inputs.

**D4-D0**

Attributes Controller Register Index Address Bits 4 To 0

Bits D4-D0 of this register select which attributes register is to be accessed at 03Clh.

**(Attributes Controller Registers)**

**Palette**

**Memory Address** Read 1FC1 Write 1FC0

**I/O Address** Read 3C1 Write 3C0

**Index**

00-0F

There are 16 palette registers. Each of these registers corresponds to one possible combination of the four video plane inputs to the attributes controller system.

Bits D5-D0 allow a dynamic mapping of text attribute or graphic color input value for the displayed color. The value of these six bits determine the color to be displayed.

Memory Address	Read 1FC1	Write 1FC0	I/O Address	Read 3C1	Write 3C0	Index	1 0
----------------	-----------	------------	-------------	----------	-----------	-------	-----

- D7** PD5/4 Select
  - . 0: Enables PD5 and PD4 to become the outputs of the palette registers.
  - . 1: Causes PD5 and PD4 to be used as bits 0 and 1 of the color select register.
- D6** PEL Width
  - . 1: Causes the video pipeline to be sampled such that eight bits are available for color selection in the 256-color mode.
  - 0: This bit should be 0 in all other modes.
- D5** PEL Panning Compatibility
  - 0: Has no effect on the output of the PEL panning register.
  - . 1: Causes a successful line compare in the CRT controller to force the output of the of the horizontal panning register to 0 until “+VSYNC” becomes active. The output then returns to its programmed value. This bit allows the panning of only the top portion of the display.
- D3** Blink/Intensity Select
  - . 0: Selects the use of bit D7 of the character attribute to be used for the background intensity.
  - . 1: Selects the use of bit D7 of the character attribute to be used for blink. This bit is also 1 to enable blinking in graphics modes.
- D2** Line Graphics Enable
  - . 0: Causes the ninth horizontal bit position of a displayed character cell to be the same color as the background.
  - 1: Causes the ninth horizontal bit position of a displayed character cell to be the same as the eighth bit position if the character code being displayed is between 0C0h and 0DFh.

- D1 Monochrome/Color Select
  - . 0: Selects color display attributes.
  - 1: Selects monochrome display attributes.
- D0 Graphics Mode Select
  - 0: Selects the alphanumeric mode.
  - 1: Selects the graphics mode.

**Address****(Sequencer Registers)****Memory Address** 1FC4**I/O Address** 3C4**D4-D0**

Sequencer Register Index Address Bits 4 to 0

The index specified by these address bits indicate the location of the register to which data is being written to or read from.

**Reset****(Sequencer Registers)****Memory Address** 1FC5**I/O Address** 3C5**Index** 00**D1**

Synchronous Reset

0: Clears and stops the sequencer at the end of a memory cycle, and the memory buses are placed in the high impedance state. This bit must be set to 0 before changing any of the following:

- D0 and D3 of 1FC5h Index 01
- D2 and D3 1FC2h
- D0, D1 and D5 of 1FDFh Index 01
- D3 and D6 of 1FDFh Index 2

**D0**

Asynchronous Reset

0: Clears and stops the sequencer at the end of a memory cycle and the DIP switch latch becomes transparent. Resetting the sequencer with this bit can cause the loss of data.

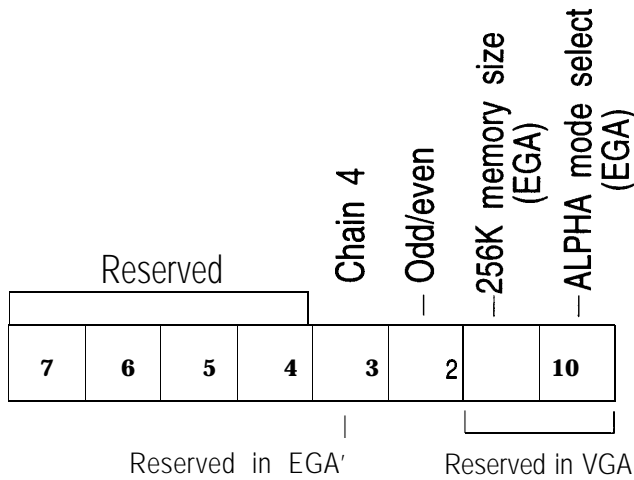

D4, D1-D0 Map B Select Bits 2, 1 And 0  
These bits are used for alpha character generation, when character attribute bit D3 is 0, according to the following table:

<i>D4</i>	<i>D1</i>	<i>D0</i>	<i>Map Selected</i>	<i>Map Location</i>
0	0	0	0	1 <sup>st</sup> 8KB of Plane 2
0	0	1	1	3 <sup>rd</sup> 8KB of Plane 2
0	1	0	2	5 <sup>th</sup> 8KB of Plane 2
0	1	1	3	7 <sup>th</sup> 8KB of Plane 2

1	1	1	7	8 <sup>th</sup> 8KB of Plane 2

Memory Address 1FC5

I/O Address 3C5

Index 04

D3 Chain 4

- . 0: Causes the system to access the data sequentially within a memory plane.
- . 1: Causes the two low-order bits A0 and A 1 to select the memory plane to be accessed by the system as follows:

<i>A1</i>	<i>A0</i>	<i>Map Selected</i>
0	0	0
0	1	1
1	0	2
1	1	3

- D2** Odd/Even Mode
- 0: Enables the system to write to planes 0 and 2 only at even addresses and planes 1 and 3 at odd addresses.
  - 1: Enables the system to write to any plane which is enabled by the plane mask register.
- D1** 256K Memory Size (EGA mode only)
- . 0 when 256K of memory is not installed. Address bits 14 and 15 are forced to 0.
  - . 1 when 256K of memory is installed. D1 should always be 1 for this multi-function video controller.
- D0** Alpha Mode Select (EGA mode only)
- . 0: Causes the graphics mode to be active. Address bits 13, 14 and 15 of the B video memory planes will be the same as those of the A video memory planes.
  - . 1: Causes the alphanumeric mode to be active. This causes address bits 13, 14 and 15 of the B video memory planes to be selected from the character map select register.

**D1-D0** DAC Status. This port returns the last access cycle to the palette.

<i>D1</i>	<i>D0</i>	<i>Most Recent Cycle</i>
0	0	Write palette cycle
1	1	Read palette cycle

Reads from the DAC Write (3C8) or DAC Status registers do not interfere with read or write cycles, and may take place at any time.

**(Graphics Controller Registers)**

**Address**

**Memory Address 1FCE**

**I/O Address 3CE**

**D3-D0**

Graphics Controller Register Index Address Bits 3 to 0  
These bits select which register is to be accessed at port 3CFh.

**(Graphics Controller Registers)**

**Set/Reset**

**Memory Address 1FCF**

**I/O Address 3CF**

**Index 00**

**D3-D0**

Set/Reset plane 3 to 0  
These bits allow the set or reset of byte values in the four video planes:

- 1: Sets the byte
- 0: Resets the byte.

This register is active when the graphics controller is in write mode 0 and enable set/reset is activated.

**Enable Set/Reset****(Graphics Controller Registers)****Memory Address** 1FCF**I/O Address** 3CF**Index** 0 1**D3-D0**

Enable Set/Reset Plane 3 to 0

These bits control the activation of the set/reset register. Setting any bit to 1 enables the corresponding bit in the set/reset register. Writing a 0 will disable the corresponding set/reset bit.

**Color Compare****(Graphics Controller Registers)****Memory Address** 1FCF**I/O Address** 3CF**Index** 0 2**D3-D0**

Reference Color

These bits represent a 4-bit color value for reference by read mode (bit D3, Index 05h, mode control register). In this mode, when the system reads from display memory, the data byte returned will have a 1 in each bit position where the data in the four memory planes matches the value in the color compare register. Only the planes enabled by the color don't care register will be tested.

**(Graphics Controller Registers)****Data Rotate****Memory Address** 1FCF**I/O Address** 3CF**Index** 03**D4-D3**

Function Select Bits 1 and 0

These two bits are used to select hardware logic functions to be performed between the video memory data latches and any data. Selected by the mode control register bits D0 and D1.

<b>D4</b>	<b>D3</b>	<b>Function</b>
0	0	Data unmodified
0	1	Logical AND with latched data
1	0	Logical OR with latched data
1	1	Logical XOR with latched data

**D2-D0**

Data Rotate Count Bits 2 to 0

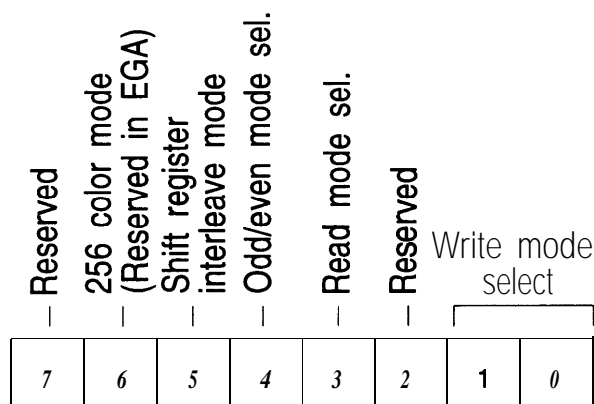

These bits produce a 3-bit binary value which specifies the number of bit positions to rotate the system data on writes to video memory in write mode 0.

**(Graphics Controller Registers)****Read Plane Select****Memory Address** 1FCF**I/O Address** 3CF**Index** 04**D1-D0**

Read Plane Select

This register is used to select the video memory plane to be read by the system. This register will select planes 3 to 0, as programmed in binary, for read operation.

Memory Address	1FCF	I/O Address	3CF	Index	0 5
----------------	------	-------------	-----	-------	-----

- D6** 256-Color Mode (VGA mode only)
- . 0: Allows the loading of the shift registers to be controlled by bit D5.
  - . 1: Causes the shift registers to be loaded in a manner which supports the 256-color mode
- D5** Shift Register Interleave Mode
- 1: Causes the shift registers in the Graphics Controller to format the serial data with odd numbered bits from both planes in the odd numbered planes and the even numbered bits from both planes in the even numbered planes.
- D4** Odd/Even Mode Select
- . 0: Makes the read plane select register control which plane the system reads data from.
  - . 1: Causes system address bit A0 to replace bit 0 of the read plane select register, thus allowing A0 to determine odd or even plane selection.
- D3** Read Mode Select
- 0: Causes the system to read data from the active video memory plane.
  - . 1: Enables the color compare register.
- D2** Reserved.
- D1-DO** Write Mode Select
- These two bits select the write mode as follows:

<i>DI</i>	<i>D O</i>	<i>Write Mode</i>
0	0	Data rotate. logical functions and set/reset are enabled in this mode.
0	1	The active video memory plane(s) are written with the contents of the 32-bit system data latches.
1	0	In this mode the bit position corresponding to the video plane address is used as the value of an 8-bit write to that video plane.
1	1	Each plane receives 8 bits of the value contained in the set/reset register for that plane. Rotated system data is ANDed with the bit mask register to give an 8-bit value which performs the same function as the bit mask register does in modes 0 and 2. In EGA this mode is the same as mode 1.

**D3-D2**

Memory Map Select Bits 1 and 0

These bits select where the video memory is mapped as follows:

D3	D2	Address
0	0	A0000 - BFFFFh
0	1	A0000 - AFFFFh <sup>(1)</sup>
1	0	B0000 - B7FFFh
1	1	B8000- BFFFFh

<sup>(1)</sup> Second video RAM window, when enabled, will occupy either B0000h to B7FFFh or B8000h to BFFFFh. See auxiliary register 0Ch.

**D1**

Odd/Even Chain Enable

- . 0: Causes A0 of the memory address bus to be used during system memory addressing.
- . 1: Allows A0 to be replaced by either A16 of the system address (if bits D3 and D2 are 0), or the odd/even page select bit from the miscellaneous output register.

**D0**

Graphics Mode Select

- . 0: Enables alpha mode and the character generator addressing system is activated.
- . 1: Enables graphics mode and the character addressing system is not used.

Data write mask

**D7-D0**

Data Write Mask Bits 7 to 0

If any bit in this register is set to 1 the corresponding bit in all planes may be altered by the selected write mode and system data.

If any bit is set to 0 the corresponding bit in each plane will not change.

Memory Address 1FD8

I/O Address 3D8

- D5** Text Blink Enable
  - . 0: Causes attribute bit 7 to be used for background intensity control.
  - . 1: Characters with attribute bit 7 high will blink and all characters will have low background intensity.
- D4** High Resolution Graphics: When in graphics mode (D1=1), D4=0 selects 320 x 200 mode and D4=1 selects 640 x 200 mode. This bit only has an effect when in graphics modes.
- D3** Display Enable
  - . 0: Blanks the display.
  - . 1: Enables the display. Bit D5 of auxiliary port 2 must be high before the display can be blanked.
- D2** Monochrome Select: This bit alters the foreground color palette in the 320 x 200 graphics mode. It has no effect in other modes. For foreground pixels, D2=0 (color) causes the blue output to have the same state as port 3D9hD5. When D2=1 (monochrome), the blue output is the same as pixel data bit CO. This bit only has an effect in the 320 x 200 graphics mode. If the CGA hardware palette is disabled (auxiliary port 3 D4=1) this bit has no effect on hardware.
- D1** Graphics Select
  - 0: Selects text mode
  - . 1: Select graphics mode.
- D0** High Resolution Text: This bit has no effect in hardware, but must be interpreted by emulation software to set up the sequencer and CRTIC. When in text mode (D1=0), D0=0 selects 40 x 25 characters and D0=1 selects 80 x 25 characters. This bit has no effect in graphics modes.

Memory Address 1FD9

I/O Address 3D9

Reserved		Alt. palette	Intensified palette	Intensity select	Red select	Green select	Blue select
7	6	5	4	3	2	1	0

- D5** Alternate Palette: In the 320 x 200 graphics mode, D5 selects one of two foreground color palettes. D5 has an effect only in color mode (port 3D8h D2=0). When D5=0, the blue video output is low for all foreground pixels. When D5=1, the blue video output is high for all foreground pixels. D5 does not change the background (CO=C1=O) color. If the CGA hardware palette is disabled (auxiliary port 2 D4=1) then this bit has no effect.
- This bit has an effect only in the 320 x 200 graphics mode.
- D4** Intensified Palette: In 320 x 200 graphics mode, D4=0 causes the foreground pixels to be intensified and D4=1 causes them to be low intensity. If the CGA hardware palette is disabled (auxiliary port 2 D4=1) then this bit has no effect.
- This bit has an effect only in the 320 x 200 graphics mode.
- D3-D0** Intensity, Red, Green, and Blue Select: In the text modes, these bits determine the overscan (border) color. In the 320 x 200 graphics mode, these bits determine the background pixel (C0=C1=0) and overscan colors. In 640 x 200 graphics mode, these bits determine the foreground pixel color.
- These bits have no effect if the CGA hardware palette is disabled (auxiliary port 2 D4=1). The overscan color is always determined by the contents of the attributes controller overscan register if the CGA overscan is disabled (auxiliary register 2 D3=1).

Memory Address Mono 1FBA Color 1FDA I/O Address Mono 3BA Color 3DA

- D7** Vertical Retrace Status (Hercules mode)
  - 0: Indicates that the CRTIC is in a vertical retrace period.
  - 1: Vertical Retrace is inactive.

**D5-D4** Diagnostic 1 And 0  
 D4 and D5 are selectively connected to two of the eight color outputs of the attribute controller. Bits D4 and D5 of the color plane enable register determine which color outputs are used.

Color Plane Register		Input Status Register 1	
D5	D4	D5	D4
0	0	PD2	PD0
0	1	PD5	PD4
1	0	PD3	PD1
1	1	PD7	PD6

- D3** This bit has no effect in Power Graphic mode.  
 Vertical Retrace: (VGA, EGA, or CGA mode)
  - 0: Indicates that video information is being displayed.
  - 1: Indicates that a vertical retrace interval is occurring.
 Video Output Status: (Hercules mode) This bit monitors the direct drive video output.
  - 0: Indicates that the driver output is high.
  - 1: Indicates that the driver output is low.
- D2** Light Pen Switch
  - 0: Indicates that the light pen switch is closed.
  - 1: Indicates that the light pen switch is open.

**Input Status Register 1 (continued)****(Misc Registers)**

- DI** Light Pen Latch
- 0: Indicates that the light pen latch is reset.
  - 1: Indicates that the light pen latch is set.
- D0** This bit has no effect in Power Graphic mode.  
Display Enable
- 0: Indicates an active display interval.
  - 1: Indicates a horizontal or vertical retrace interval.

Memory Address 1FDE

I/O Address 3DE

A read from the auxiliary index register clears the trap flip-flop and returns the TRAP output to its inactive state. The CRTC FIFO overflow flag is also reset and the FIFO is prepared for reads. Software must wait for 3 BUSCLK cycles (210 nS at 14.318 MHz) before reading the FIFO.

- D7 (R): Trap Flip-Flop: If the ATHENA caused a trap interrupt then D7=1. This bit will only be 1 for the first read after a trap interrupt. Reading the auxiliary Index register clears this flag and returns the TRAP output to its inactive state.
- D6 (R): CRTC FIFO Not Empty: If a CRTC emulation trap condition occurred and the CRTC FIFO is not empty then reading D6 returns 1. This flag is cleared by reading all data from the CRTC FIFO.  
 (W): FIFO Reset: Writing a 1 to D6 will reset the CRTC FIFO register and overflow flag. A 0 must be written to D6 before the FIFO can be used again.

- D5** (R). CRTC FIFO Overflow: If more than 4 writes occurred to CRTC registers since the last trap interrupt service (the CRTC emulation FIFO has overflowed) then D5=1. This bit will only be 1 for the first read after a trap interrupt. Reading the auxiliary Index register clears this flag.
- D4** (R). Miscellaneous Trap Flag: If D4=1, a trap was generated which was not a CRTC emulation trap. This indicates that one of the bits in the trap flag register is set.
- D3-D0** (R/W). Auxiliary Register Index: Bits D3-D0 of this register select which auxiliary register is to be accessed at port 3DFh.

**Mode Control**

**(Auxiliary Registers)**

Memory Address 1FDF	Read	3DF	Index	00
---------------------	------	-----	-------	----

- D7** Analog Monitor Disable: When D7=0, the analog monitor synchronous drivers are enabled. If D7=1 then the analog monitor drivers are disabled. The drivers are also disabled if port 3C2h, D4=1.
- D6** TTL Monitor Disable: When D6=0, the TTL monitor drivers are enabled. If D6=1 then the TTL monitor drivers are disabled.
- D5** Sequencer Speed: D5=0 selects sequencer cycles with high CPU interleave. High CPU interleave is usually selected with sequencer clocks of less than 30 MHz. Higher sequencer clock frequencies require D5=1 to select low interleave cycles which meet the DRAM timing specifications. Halt the sequencer by a synchronous or asynchronous reset before changing this bit.
- D4** CRTC 14-Bit Address Select: If D4=0 then the CRTC start address, cursor address, and light pen registers and address counter are 16-bit. If D4=1 then the most significant 2 bits of the registers and counter are forced to 0. This is used for 6845 CRTC emulation.
- D3** CRTC Light Pen Read Select: D3=0 causes the vertical retrace start and end registers to be read at CRTC register addresses 10h and 11 h. D3=1 causes the light pen registers to be read at those addresses.

**D2** CRTC Select: The VGA CRTC is used when D2=0 and the EGA CRTC is used when D2=1.

**D1-D0** Mode Control 1 and 0: These bits select which display adapter the ATHENA is to emulate. They determine which registers may be accessed and which hardware emulation functions are enabled. Halt the sequencer by a synchronous or asynchronous reset before changing these bits.

<i>D1</i>	<i>D0</i>	<i>Mode</i>
0	0	VGA
0	1	EGA
1	0	CGA
1	1	MDA/Hercules

<b>Memory Address</b> 1FDF	<b>I/O Address</b> 3DF	<b>Index</b> 01
----------------------------	------------------------	-----------------

**D7** Test Enable: For normal operation, D7=0. To enable test functions, D7=1. When test functions are enabled, auxiliary register 4 (general storage) can be used to control ATHENA's hardware test functions.

**D6** BUSCLK Clock Select: Port 3C2h is used to select the clock source. Halt the sequencer by a synchronous or asynchronous reset before changing this bit. The state of D6 affects the clock input selection as follows:

<i>3C2h</i>	<i>D6 = 0</i>	<i>D6 = 1</i>
<i>D3, D2</i>		
00	CLKINO	CLKIN1÷2
01	CLKIN1	CLKIN3
10	CLKIN2	CLKIN2
11	BUSCLK	CLKIN1

**D5** Display Panel Enable: The ENABLE output (pin 70) is controlled by this bit, and is used to enable the display panel. The state of the ENABLE pin is the same as D5.

- D4** FlexFont Enable: Normal text mode font selection is in effect when D4=0. When D4=1, attribute bits D6-D4 are used to select from one of eight simultaneously displayable fonts. The background color bits are disabled (forced low), attribute bit D7 (intensity/blink) still has effect, and D3 is not used for font selection.
- D3** HR256 Select: When this bit is high, the required hardware functions are enabled to permit a high resolution, 256 color, display mode. This function is enabled only when in VGA mode on a CRT display. Halt the sequencer by a synchronous or asynchronous reset before changing this bit.
- D2** CPU A16 Select: When high, CPU page select bit 0 (DO) is replaced by address bit A16. This allows the use of a 128K memory map (A0000-BFFFFh) so that the CPU can access 2 pages in VGA 256 color mode without page switching.
- D1** Simultaneous Write Enable: When the 512 KB memory option is selected internal DRAM address bit 16 selects one of /CAS0 or /CAS 1 to go active during a memory cycle. During a CPU write cycle both /CAS0 and /CAS 1 will go active if the simultaneous write enable bit is high. This is required in alphanumeric modes where multiple pages are desired. The character font must be loaded into both banks of plane 2 DRAM so that characters are displayed properly when ASCII and attribute data are taken from the upper DRAM bank.
- DO** Extended Page Enable: When this bit is 0 display memory in 13h is limited to 1/4 of the installed DRAM. This gives full compatibility with the IBM VGA. Multiple display pages are available when this bit is 1. If D3 of this register (high resolution select) is 1 then the extended page enable should also be 1.

The extended page enable bit only affects CPU cycle addressing if D3 of sequencer register 4 (Chain 4) is 1. If DO is 0 then A0 and A1 of the DRAM address are forced low. If DO is 1 then page select bits 1 and 0 of the auxiliary register 9 are used for the low DRAM address bits.

If D3 (high resolution select) of auxiliary register 1 is 0, then DO affects CRT cycle addressing. If bit D6 (double word mode) of CRTC register 14h is 1, and DO is 0, then both A1 and A0 are 0 and the display wraps in the same way as the IBM VGA. If DO is 1, then the high CRTC counter bits replace A0 and A1 so that more memory may be accessed for high resolution displays.

Memory Address 1FDF	I/O Address 3DF	Index 0 2
---------------------	-----------------	-----------

This register determines the degree of hardware emulation desired and also provides functions required for software emulation.

- D7**      VGA/EGA CRTC Register Mask
  - 0: Allows access to all VGA/EGA CRTC registers.
  - . 1: Prevents access to CRTC registers for which traps are enabled by D4 and D5 of the trap control register.
  
- D6**      CRTC Offset Register LSB: This bit is used to achieve odd CRTC offset register values so that full software-aided emulation of the 6845 CRTC is possible. It should be enabled, D6= 1, at all times.
  
- D5**      CGA/Hercules Blanking Enable
  - 0: Forces the display to be enabled in CGA and Hercules modes. This overrides the display enable bits in registers 3B8h and 3D8h so that the display will not flicker during scrolling.
  - . 1: Allows registers 3B8h (Hercules mode) and 3D8h (CGA mode) to control the display if hardware emulation is enabled.
  
- D4**      CGA Hardware Palette Disable
  - . 0: Causes the CGA hardware palette to be used in CGA mode if D2=0.
  - . 1: Allows the use of the attributes controller palette and enables extra trap conditions to aid in emulation of CGA register 3D9h. This allows flexibility in the way CGA colors are displayed so that various monitors can be used.
  
- D3**      CGA Overscan Disable
  - . 0: Causes the overscan (border) color to be taken from CGA register 3D9h as required in CGA mode if D2=0.
  - 1: Forces the overscan color to be taken from the attributes controller overscan register. This allows software control of the overscan. The overscan must be forced to black on monitors which are not blanked during retrace.

- D2** CGA Hardware Emulation Disable
- 0: Enables hardware emulation for CGA ports 3D8h and 3D9h.
  - . 1: Hardware emulation is disabled so that the contents of 3D8h and 3D9h have no effect on hardware. Extra trap conditions are enabled to permit software emulation. The CGA overscan and hardware palettes are also disabled.
- D1** Hercules Page 1 Access Enable
- . 0: Allows Hercules port 3BFh to control CPU access to Hercules memory page 1 (B8000-BFFFFh) if DO=0.
  - . 1: Enables CPU access to memory page 1 when in Hercules mode. This allows software to control emulation of Hercules port 3BFh.
- D0** Hercules Hardware Emulation Disable
- . 0: Enables hardware emulation for Hercules ports 3B8h and 3BFh.
  - 1: Hardware emulation is disabled so that the contents of 3B8h and 3BFh have no effect on hardware. Extra trap conditions are enabled to permit software emulation.

7	6	5	4	3	2	1	0											

This register determines which conditions cause a trap interrupt (NMI) and also controls access to the VGA CRTC registers and CRTC emulation FIFO.

- D7** VGA Register Mask
- . 0: Allows access to VGA registers in the 3C0-3CFh. This bit is used by emulation software when it must alter the VGA registers. Power-up default is D7=0.
  - 1: Causes the VGA registers in the 3C0-3CFh range to be masked from CPU access.
- D6** Cursor Trap Enable
- . 0: Trap disabled (power-up default)
  - 1: Enables traps on writes to cursor locations.

- D5** CRTC Extended Trap Enable
- 1: Enables traps and FIFO writes for CRTC registers OC-OFh.
- D4** CRTC Emulation Trap Enable
- 1: Enables trap interrupts on writes to CRTC registers 00h-0Bh and 10h-18h. Writes to the CRTC emulation FIFO are also enabled. This is used for software-aided emulation of the 6845, VGA, or EGA CRTC's. See the trap conditions described elsewhere.
- D3** CRTC Mode Switch Trap Enable
- 1: Enables trap interrupts to CRTC ports which might indicate that an automatic mode switch is required. The CRTC Index register can be accessed at port addresses in the 3BXh and 3DXh ranges. See the trap conditions described elsewhere.
- D2** Hercules Trap Enable
- 1: Enables trap interrupts on writes to Hercules ports. CPU access to Hercules ports 3B8h and 3BFh is also enabled. See the trap conditions described elsewhere.
- D1** CGA Trap Enable
- 1: Enables trap interrupts on writes to CGA ports. CPU access to CGA ports 3D8h and 3D9h is also enabled. See the trap conditions described elsewhere.
- D0** . 1: Enables trap interrupts on writes to ports in the 3C0h-3CFh addresss range. Refer to the trap conditions described elsewhere.  
Enabling the traps does not enable CPU access to the registers. The VGA registers must be unmasked (see D7) before the CPU can access the registers.

Memory Address 1FDF	I/O Address 3DF	Index 04
---------------------	-----------------	----------

**D7-D0** General Storage and Test Control

This register is normally used for flag storage by the BIOS software. When D7 of the extended function register (test enable) is high, these bits control ATHENA’s test functions. Some of the input and output pins can be selected to drive or monitor internal signals of the ATHENA for testing.

Test inputs are enabled when D2 is high and D7 of auxiliary register 1 is high. Bits D0 and D1 are used to select which internal signals are to be driven:

Input Pin	D1,D0=00	D1,D0=01	D1,D0=10	D1,D0=11
MONSO	TMSYNC	TMAMUX	<i>TMAMUX</i>	TMDE
MONS 1	TMREFSH	TMBMUX	TMBMUX	TMBLANK
FEAT0	/TMDREN	/TMDREN	/TMDREN	TMCURSR
FEAT1	TMVDE	TMCRT	/TMCPUL	TMUNLIN
PANEL		TMCAL	/TMCRTL	TMPVRTC
LPENSW		TMCCLK	TMHRHLT (/TMDREN=1)	TMLCV
UP		/TMTOP		TMLCVBT
DOWN			TMDEBT	

Test outputs are enabled when D5 is high and D7 of auxiliary register 1 is high. Bits D3 and D4 are used to select which internal signals are available at the outputs:

Output Pin	D4,D3=00	D4,D3=01	D4,D3=10	D4,D3=11
FC0	/SQATLD	SQCRTLO	CRISYNC	CRISYNC
FC1	/SQCCLK	SQCRTL1	CR8RFSH	CR8RFSH

----------------------------	------------------------	-----------------

---

- D3-D0** CPU Page Select 3-O: Up to 16 pages of memory are available in the 320 x 200 pixel, 256 color, graphics mode of the VGA. When in this mode these four bits select which 64K page the CPU can access. These bits take effect when one of either D3 of the extended function register 1, or D6 of graphics controller register 5 is high.

Memory Address 1FDF	I/O Address 3DF	Index 0 A
---------------------	-----------------	-----------

- D7** IRQ Disable: When D7=1 the IRQ output is prevented from going to the active state. This gives compatibility with the ISA bus version of the IBM VGA.
- D6** DIP Switch Latch Enable: When D6 is high the DIP switch inputs (located in auxiliary register 07) are latched on the rising edge of the sequencer reset bit.
- When D6 is low the DIP switch input values are not disturbed by subsequent sequencer resets.
- D5** (R). Auxiliary Clock Status: This bit is always read as 1.
- D4** CRTC Extended Address Enable: When D4 is low, the DRAM address bits 17 and 16 are low and only 256 KB of memory can be accessed. This is used to achieve full EGA and VGA compatibility when extended memory configurations are selected.
- When D4 is high 18-bit addressing is enabled. Bits D2 and D3 of auxiliary register 9 form the high address bits on CPU accesses to DRAM. The CRTC address counter is extended to 18 bits to allow the display of any area of memory.
- D3-D2** CRTC Cursor Address Bits 17,16: These are the most significant bits of the cursor address register when 18-bit CRTC addressing is used for expanded memory access.
- D1-DO** CRTC Start Address Bits 17,16: These are the most significant bits of the start address register when 18-bit CRTC addressing is used for expanded memory access.

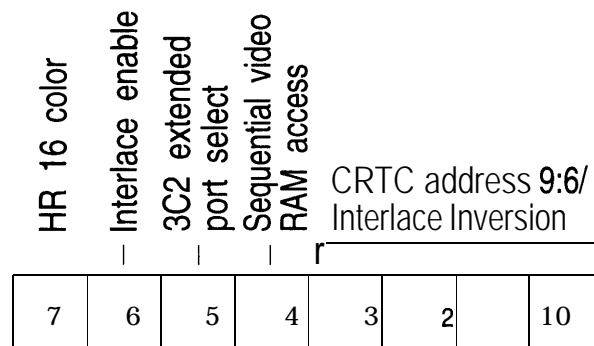

Memory Address 1FDF	I/O Address 3DF	Index 0C
---------------------	-----------------	----------

- D7 Auxiliary Window Disable
- 0: Enables the second video RAM window.
  - 1: Disables the second video RAM window.

**D4-D0** 32K Page Select Bits 4-0: Up to 16 pages of memory are available in the 320 x 200 pixel, 256 color, graphics mode of the VGA for the second video RAM window. When in this mode these four bits select which 64K page the CPU can access. These bits take effect when D7 of this register is low and one of either D3 of the extended function register 1, or D6 of graphics controller register 05 is high.

Memory Address 1FDF	I/O Address 3DF	Index OD
---------------------	-----------------	----------

- D7 HR16 Color: When this bit is high, and the HR256 mode is enabled, the sequencer runs in HR16 (high resolution, 16 color) mode while the attributes controller and the graphics controller run at twice the clock speed of the sequencer. Note that all horizontal values in the CRT controller are divided by two and that byte pan pans by 16 pixels instead of 8 in all VGA 16 color planer modes.
- When D7 is low this mode is disabled.

**D6** Interlace Enable

- 0: The interlace mode is disabled.
- 1: This bit enables the interlace mode. In this mode CRTC counter address bits (6 to 9) are inverted every other vertical frame and the VRTC signal is delayed for one half of a horizontal line every other vertical frame. The VRTC signal is delayed on the opposite frame to the address being inverted. To use this mode select the CRTC address bits to be inverted and set the Interlace Enable bit. CRTC register 06, DO, inverts every other frame to give an odd total of lines for every two frames. The value in this register must be even in interlace mode and the logical horizontal line size must be double the display size.

**D5** 3C2 Extended Port Select

- 0: /EXPWR responds to I/O writes at address 3CBh as well as 3CDh.
- 1: Allows the /EXPWR signal to respond to I/O writes at address 3C2h

**D4** Sequential Video RAM Access

- 0: Video data is stored one byte every four sequencer cycles.
- 1: This bit enables the HR256 sequencer cycles to store video data sequentially in video RAM. This supports a 16 color planer memory map.

**D3-D0** CRTC Address Bits 9 to 6/Interlace Inversion  
 These four bits are CRTC high address bits 9 through 6 and are only valid in interlace mode. Normally only one bit is selected. The following table shows the relationship between the bit selected, and the address and mode selected.

CRTC ADDRESS BIT	<u>MODE</u>		
	16Color	HR16	HR256
A6	512	1024	512
A7	1024	2048	1024
A8	2048		2048
A9	4096		4096

<b>Memory Address</b> 1FDF	<b>I/O Address</b> 3DF	<b>Index</b> O E
----------------------------	------------------------	------------------

**D7-D0** Counter Value Bits 7 to 0: This register provides a vertical sync timing adjustment for interlaced displays (interlace vertical retrace only). The value of these bits are compared to the horizontal count every other frame to provide a corrected vertical sync position. A value of zero in this register causes the horizontal total to be divided in half.

**(Configuration) Video Subsystem Access/Setup Enable**

<b>Memory Address</b>	<b>I/O Address</b> 46E8
-----------------------	-------------------------

This register is only activated when ATHENA is reset with VGA enabled (refer to the vgaen strap description in Section 3.6.3 for more details).

- D3 Video Subsystem Enable.
  - . 0: Disables the video subsystem
  - . 1: Enables the video subsystem
- D4 Video Subsystem Setup.
  - . 0: Disables access to I/O address 102
  - . 1: Enables access to I/O address 102

Memory Address

I/O Address 102

This register is only activated when ATHENA is reset with VGA enabled (refer to the VGAEN strap description in Section 3.6.3 for more details).

DO

Video Subsystem Enable.

- 0: Disables the video subsystem
- 1: Enables the video subsystem

---

## **Chapter 6: Hardware Interface**

***T****his chapter explains the hardware interface of the ATHENA chip. It describes both the input from the host PCI and ISA interfaces and the output, which can be channeled directly to the RAMDAC and VRAM, or through a multiplexer or DUBIC chip (if either are present).*

## 6.1 Introduction

The ATHENA chip has been designed in such a way as to minimize the amount of external logic required to implement a board. It includes:

- . A direct interface to the ISA bus. In this case, the bus can be driven exclusively by means of buffers.
- A direct interface to the PCI bus, including a dedicated bus for external devices (this avoids the requirement for a buffer on the data bus).
- The PCI interface can be used to interface to any 32-bit bus, with glue logic.
- All necessary support for external devices, such as ROM, the Matrox DUBIC chip, RAMDACs, as well as an expansion decode strobe. These devices can be interfaced without the need for glue logic.
- . A 'No DUBIC' operation mode which eliminates the need for a DUBIC chip to drive the video data.
- . A 'No MUX' operation mode which eliminates the need for an external multiplexer in 'No DUBIC' mode.
- . A direct connection to the VRAM.

## 6.2 Host Interface

### 6.2.1 PCI Interface

The PCI Interface block diagram (Figure 6-1) shows how to connect ATHENA to the PCI bus, as well as to the local resources.

#### 6.2.1.1 PCI Bus Operation

##### Command Decoding

The following cycles on the PCI bus will perform the operations specified below on the ATHENA chip (when decoding recognizes the access):

<i>C/BE&lt;3:0&gt;#</i>	<i>Command Type</i>	<i>Operation</i>
0000	Interrupt acknowledge	None
0001	Special cycle	None
0010	I/O read	I/O read
0011	I/O write	I/O write
0100	Reserved	None
0101	Reserved	None
0110	Memory read	Memory read
0111	Memory write	Memory write
1000	Reserved	None
1001	Reserved	None
1010	Configuration read	Configuration register read
1011	Configuration write	Configuration register write
1100	Memory read multiple	Memory read
1101	Dual address cycle	None
1110	Memory read line	Memory read
1111	Memory write and invalidate	Memory write

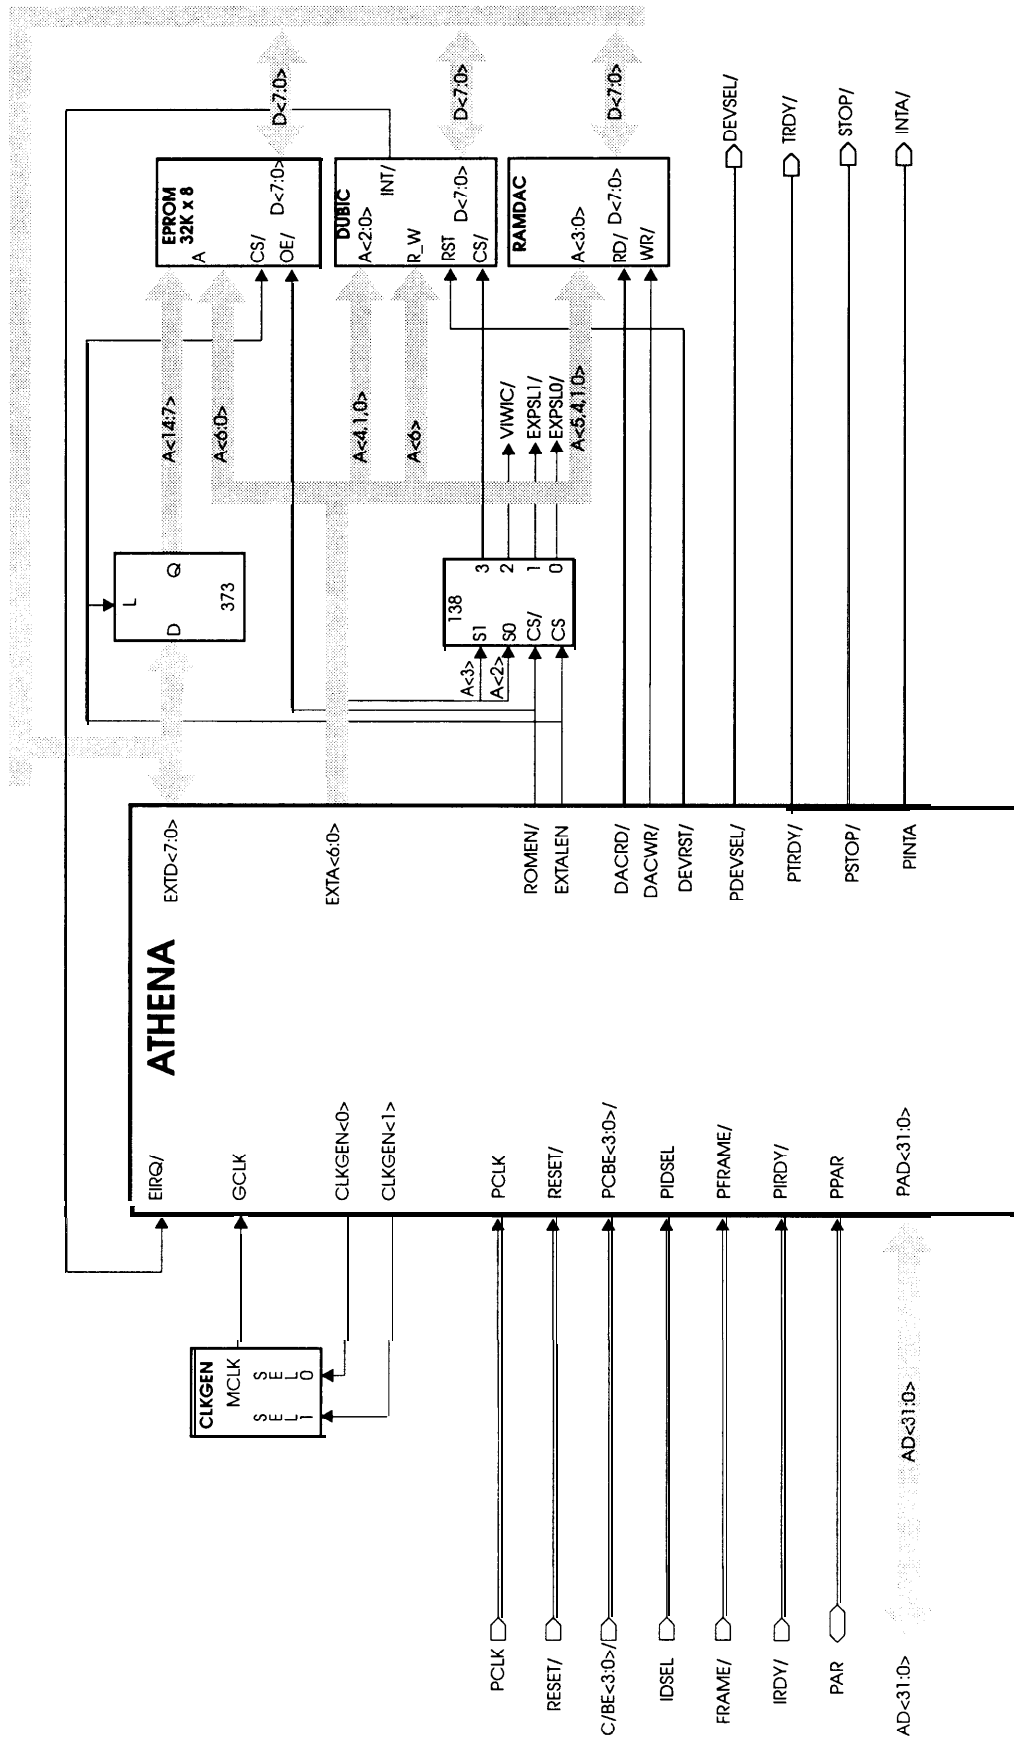

Figure 6-1: PCI Interface

## DEVSEL

Because ATHENA is a medium-speed device, it will respond to DEVSEL in the second clock after FRAME/ is asserted.

### Disconnect and Retry

Disconnect and retry are used in order to minimize the latency time on the bus. Refer to Section 6.2.1.2 for more information about when the disconnect and retry are used.

### Burst Mode

Since ATHENA supports burst mode, address generation must be a counter. Because a 5-bit counter is employed, a disconnect will be generated every 32 dwords.

<i>AI</i>	<i>A0</i>	<i>Burst Order</i>
0	0	Linear incrementing (disconnect at every 32 dword boundary)
0	1	Disconnect after each transfer
1	X	Disconnect after each transfer

### Configuration Access

During a configuration access, A<1:0> have a different function than normal - they indicate if the access is Type 0 or 1. ATHENA responds only to Type 0 accesses, since it is a device on the PCI bus.

<i>AI</i>	<i>A0</i>	<i>Access Type</i>
0	0	ATHENA access when idsel is asserted
0	1	Configuration access to another PCI bus (bridge)
1	X	Reserved

### Snooping

ATHENA can perform snooping under the following two conditions:

1. When the VGA RAMDAC snooping bit is active.
2. When the 46E8 enabling feature is activated.

This cycle operates in two different ways:

- If there is no room in the input buffer then ATHENA takes control of the bus and a retry cycle is performed.
- If there is room in the input buffer then the data will be loaded when the data transfer occurs on the PCI bus.

Under normal conditions, only a subtractive agent will respond to the access. In this case, the snoop mechanism will function correctly. For other than normal conditions:

- If there is another device on the PCI bus that responds to this mapping, or if another device is performing the snoop mechanism with retry capabilities, then this will result in contention on the PCI bus.
- Burst mode is not supported in the snooping area. This is not supposed to append since bridges are not allowed to 'burst' consecutive I/O accesses, and CPUs do not perform burst on I/O accesses.
- If another device on the PCI bus performed the shortest cycle, then ATHENA will not be able to get the data, but the state machine will be able to recover.

### 6.2.1.2 PCI Cycles

The following resources are accessible to the PCI interface:

- . Configuration register writing
  - Input buffer writing to:
    - I/O
    - VGA frame buffer
    - Power Graphic mode memory space
- . Configuration register reading
- . Output buffer reading:
  - Power Graphic mode memory space (and pseudo DMA range when enabled)
- . Direct reading from:
  - I/O
  - VGA frame buffer
  - Power Graphic mode memory space (except pseudo DMA range when enabled)
  - EPROM

#### Configuration Register Writing

These cycles will be of fixed length as far as ATHENA is concerned (no wait states are added by the master). To avoid burst, a disconnect cycle is performed when TRDYN is asserted.

#### Input Buffer Writing

This cycle operates under the following parameters:

- . If there is room in the input buffer, the cycle is of fixed length.
- If there is no room in the input buffer, a retry cycle is performed.
- A retry cycle is performed when a 32 dword boundary is passed.
- A disconnect cycle is performed when TRDYN is asserted, to avoid burst during I/O access.

#### Configuration Register Reading

These cycles will be of fixed length as far as ATHENA is concerned (no wait states are added by the master). A disconnect cycle is performed when TRDY/ is asserted, to avoid burst.

#### Output Buffer Reading

This cycle operates under the following parameters:

- If there is data in the input buffer, then a retry cycle of fixed length is performed.
- . If there is data in the output buffer, then the cycle is of fixed length.
- If there is no data in the output buffer, then a retry cycle of fixed length is performed.

## Direct Read

This cycle operates under the following parameters:

- If there is data in the input buffer, then a retry cycle of fixed length is performed.
- . If there is no data in the input buffer, then wait states are generated until ATHENA acknowledges the access. A disconnect cycle is performed when TRDY/ is asserted, to avoid burst.

### 6.2.1.3 Bus Sizing

The PCI bus does not support bus sizing. However, internal circuitry performs the bus sizing for the following devices: EPROM, I/O accesses, VGA register space in 16K windows (offset 1F00h-1FFFh), and the VGA frame buffer.

When bus sizing is performed in the PCI interface, the access is performed in **LSB/MSB** order.

### 6.2.1.4 External Devices

The standard external devices can be connected to the ATHENA as shown in Figure 6-1.

When only the EPROM and RAMDAC are present, the decoder (138) is not required. If the DUBIC or another external device is required, then the decoder must be added to the design.

When accessing the 'external devices' memory space (offset 3C00h-3FFCh), all devices within this memory space are 8-bit, connected to byte 0 in the double-word address boundary. Byte, word and double-word accesses are allowed, but only byte0 is valid. Byte3, 2, and 1 are masked by ATHENA.

You can add other devices by using the EXPSSL/ signal and external circuitry. Refer to Table 4-4 ('ATHENA Power Graphic Mode Memory Mapping') and the expdev bit of the CONFIG register description (which starts on page 5-52) for details about EXPSSL/.

- ❖ Note: In the PCI configuration, the EXPSSL/ signal is never activated with I/O commands.

The RAMDAC can be accessed by ATHENA in two distinct ways: in VGA mode by an I/O access, or in Power Graphic mode by a memory access. For I/O access to the RAMDAC, the ATHENA chip guarantees the recovery time between accesses to the palette that are required by some RAMDACs. This is guaranteed for pixel clocks that are greater than 10 MHz. For memory access to the RAMDAC, ATHENA does not guarantee the recovery time. In this case, the recovery time must be guaranteed by software.

## 6.2.2 ISA Interface

The ISA interface block diagram (Figure 6-2) shows how to connect ATHENA to the ISA bus, as well as to the local resources.

### 6.2.2.1 Bus Sizing

Since bus sizing is supported in ISA systems, there are only two limitations:

1. The first limitation occurs when accessing the 'vgareg' portion of the ATHENA memory space (offset 1F00h-1FFFh), with the ATHENA configured as a 16-bit device. Note that the 'vgareg' memory space can be accessed only in Power Graphic mode (vgaen = '0').

Only byte accesses are allowed in this mapping. ATHENA will perform byte swapping from, or to, the byte0 of the internal data bus, since all 'vgareg' devices are connected to byte0. If an access is performed at an even address, the odd byte will be ignored, and if an access is performed at an odd address, the even byte will be ignored.

2. The second limitation occurs when accessing the 'external devices' memory space (offset 3C00h-3FFCh), in 8 or 16-bit mode. All devices in this memory space are 8-bit devices connected on AD<7:0>, and mapped into a double word address boundary. Byte, word and double word accesses are allowed, but only byte0 is valid. Byte3, byte2, and byte1 must be masked.

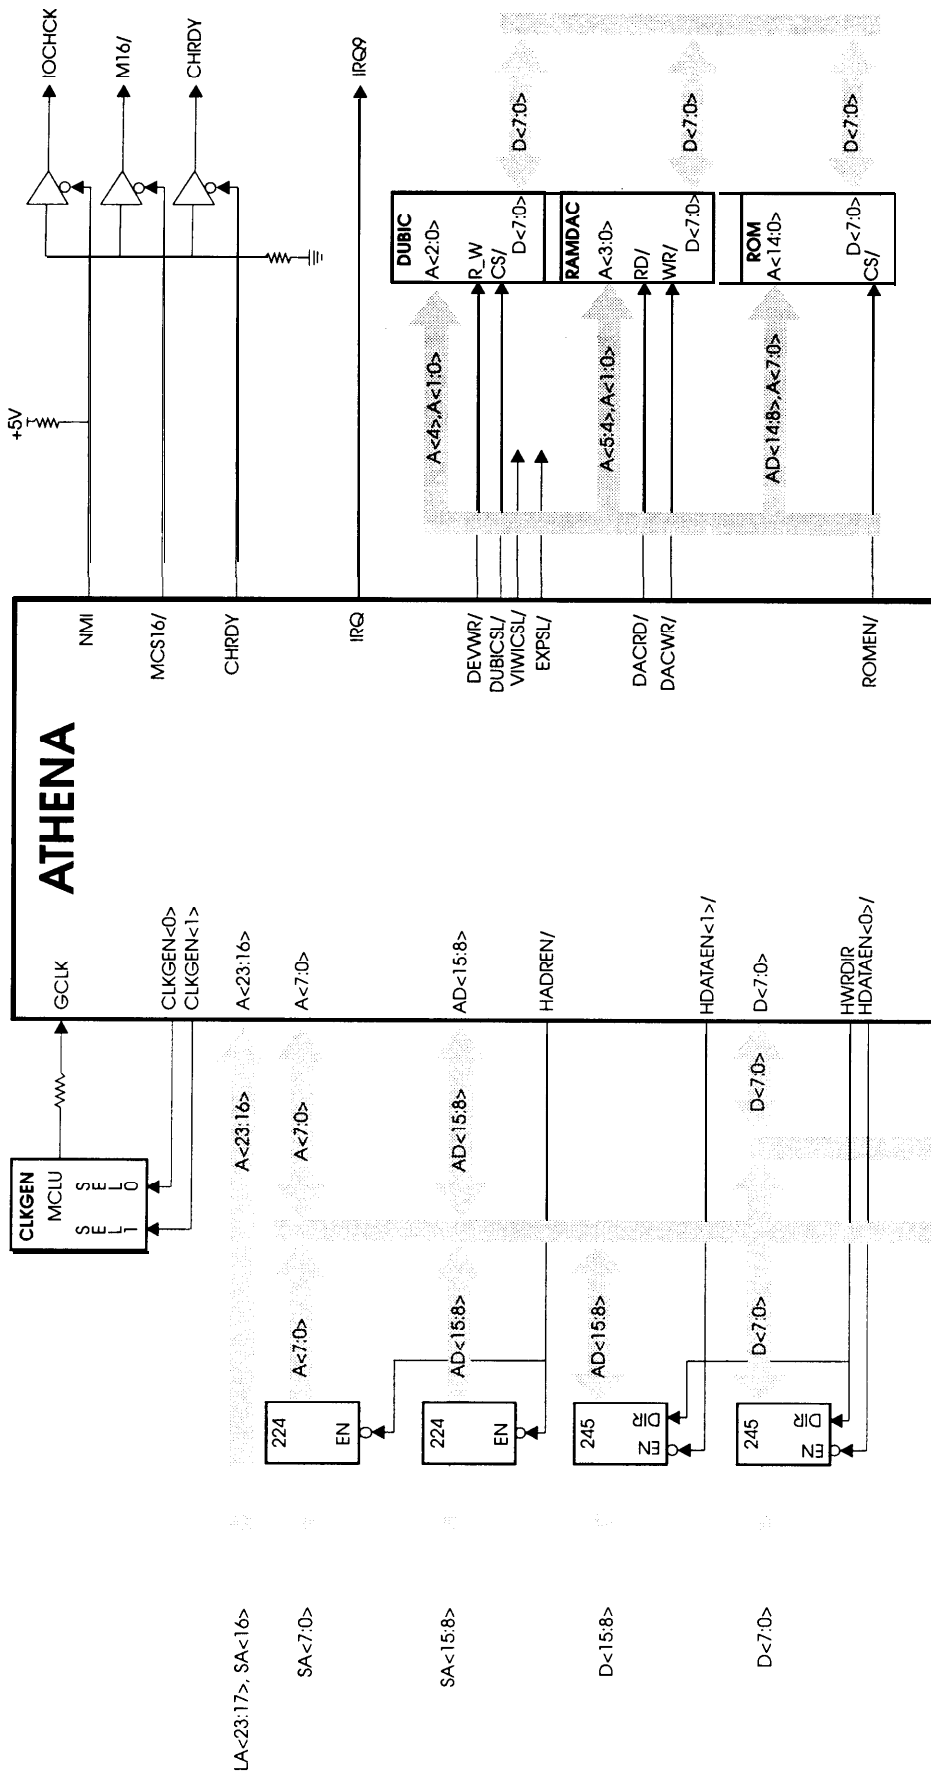

Figure 6-2: ISA Interface

### 6.2.2.2 External Devices

The standard external devices can be connected to the ATHENA as shown in Figure 6-2. Some timing restrictions for the external address and data buffers are assumed in order for the ATHENA chip to function properly. In addition to satisfying all ATHENA and system timings, the following constraints must also be respected.

1. The address buffers (244 type) must have a propagation delay of 10 ns or less, and an enable time of 11 ns or less.
2. The data transceivers must be able to drive the elevated capacitive load of the system data bus, and still guarantee a propagation delay of 10 ns or less and an enable time of 12 ns or less.

ATHENA provides the necessary control signals (**HADREN/**, **HWRDIR**, and **HDATAEN<3:0>/**) for the address and data buffers. When they are used as indicated, there is no contention on the multiplexed address and data bus. If these signals are modified or not used at all, extreme caution must be exercised, because the behavior of the multiplexed bus is not always obvious. During external device accesses in particular, the address is driven by ATHENA and not by the address buffer. Refer to Section A.2.3 for more information.

All external devices such as the RAMDAC, DUBIC, and ROM must be connected to byte 0 of the data bus. These devices are memory mapped to be double-word aligned. Only byte 0 accesses are allowed; accesses to other bytes will cause errors. Word and double-word accesses will cause unpredictable results.

You can add other devices by using the **EXPSL/** signal and external circuitry. Refer to Table 4-4 ('ATHENA Power Graphic Mode Memory Mapping'), Table 4-6 ('I/O Mapping'), and the **expdev** bit of the **CONFIG** register description (which starts on page 5-52) for details about **EXPSL/**. Since the **EXPSW** signal can be active in various memory and I/O ranges, you must take care to qualify the strobe to limit accesses to the desired range. Specifically, **EXPSW** may be active in the VGA I/O space, where only the 16 least significant address bits are decoded. Depending on how the strobe is used, it may be necessary to qualify **EXPSW** with the memory or I/O command strobe to eliminate any undesired effects.

The ATHENA chip doesn't provide any mechanism to guarantee the recovery time between accesses to the palette that some RAMDACs require. This constraint is often a function of the pixel clock, and can often become significant in length.

The RAMDAC can be accessed by ATHENA in two distinct ways: in VGA mode by an I/O access, or in Power Graphic mode by a memory access. In an ISA implementation, the I/O accesses are rarely a problem since the ISA specification for I/O accesses is usually sufficient to guarantee the RAMDAC constraint. In any other implementation, this parameter must be guaranteed by the hardware (through additional circuitry, if necessary) in order to guarantee VGA software compatibility. For memory accesses, since there is no software compatibility issue, the solution can be implemented in the software if it isn't guaranteed by the hardware.

### 6.3 VRAM Interface

ATHENA connects directly to the VRAM. All addresses and control signals of the random port are generated from ATHENA. Serial data and control lines are interfaced directly to the RAMDAC or to the DUBIC chip.

Different memory banks can be populated in order to achieve different resolutions. In every case, the fbm field of the OPMODE register selects a specific memory mapping. There are three major groups:

1. fbm = 000X. In this case no interleave is performed on the memory. In No DUBIC mode, the video data is generated either using external multiplexers, or by controlling the VRAM output enable. In DUBIC mode, only one DUBIC is required to generate the video data. These modes can support 8, 16, or 32 bits/pixel formats. This group only supports 1MB VRAM.
2. fbm = 00 1X or fbm = 1010. In these cases no interleave is performed on the memory. In No DUBIC mode, the video data is generated either using external multiplexers, or by controlling the VRAM output enable. In DUBIC mode, only one DUBIC is required to generate the video data. These modes can support 8, 16, or 32 bits/pixel formats. This group supports 2MB VRAMs.
3. fbm = 0 1 XX. In these cases, interleave is performed on the memory, and two DUBICs are required to generate the video data. These mapping groups only support 24 or 32 bits/pixel. Refer to Section 3.2.1 for additional information on memory configuration.
  - Z\* Tables 6-1 and 6-2 show the possible configurations in No DUBIC mode and DUBIC mode, respectively. If a configuration is not listed, it is not supported, and can't be used. The columns under the resolutions represent the supported pixel depths.

Mapping Group 1									Resolution						
Memory Bank									768 x 576						
0	1	2	3	4	5	6	7	8	fbm	640 x 480	800 x 600	1024x 768	1152 x 882	1280 x 1024	1600 x 1200

**Table 6-2: Frame Buffer Config. (DUBIC Mode)**

**Legend:**

- X Bank is fully populated
- P Bank is partially populated: VD<55:32> and VD<23:0>
- 0 Bank is optionally populated

The nine memory banks are explained below:

- Bank 0:** 8 x 128K x 8 VRAM. This memory is used as the frame buffer and is connected to VD<63:0>.
- Bank 1:** 8 x 128K x 8 VRAM. This memory is used as the frame buffer and is connected to VD<63:0>. This bank can also be used as a Z depth buffer when fbm = 1.
- Bank 2:** 8 or 6 x 256K x 8 VRAM. This memory is used as the frame buffer. In the fbm = 2,3 configurations, eight chips are used, connected to VD<63:0>. In the fbm = 4, 5, 6, and 7 configurations, six or eight chips are used. The six-chip configuration is for 24 bits/pixel, and the chips are connected to VD<55:32> and VD<23:0>.
- Bank 3:** 8 or 6 x 256K x 8 VRAM. This memory is used as the frame buffer. In the fbm = 2,3 configurations, eight chips are used, connected to VD<63:0>. In the fbm = 4, 5, 6, and 7 configurations, six or eight chips are used. The six-chip configuration is for 24 bits/pixel, and the chips are connected to VD<55:32> and VD<23:0>. This bank can also be used as a Z depth buffer when fbm = 2 and fbm = 3.
- Bank 4:** 8 or 6 x 256K x 8 VRAM. This memory is used as the frame buffer. The eight chip configuration is used for 32 bits/pixel, and the chips are connected to VD<63:0>. The six chip configuration is used for 24 bits/pixel, and the chips are connected to VD<55:32> and VD<23:0>.
- Bank 5:** 4 x 256K x 16 DRAM. This bank is used as off-screen memory or as a depth buffer. Bank 5 is connected to VD<63:0>.
- Bank 6:** 1 x 256K x 4 VRAM. This memory is used as the ZTAG. It is connected to ZTAG<3:0>.
- Bank 7:** 1 x 64K x 16 DRAM. This memory is used to fill up the VRAM Data bus to 64 bits for configurations where only 24 bits are supported. This allows some offscreen areas to be used for font storage. This bank is connected to VD<63:56> and VD<31:24>.
- Bank 8:** 4 x 256(64)K x 16 DRAM. This memory is used as off-screen memory or as a depth buffer. Bank 8 is connected to VD<63:0>.

### 6.3.1 Memory Interleave

In order to have enough bandwidth for 1280 x 1024 x 24 bits, some modes use interleave schemes to address the frame buffer. The memory interleave is selected when fbm = 01XX. Interleave is performed only in the VRAM (Banks 2, 3, and 4). The interleave is done on a four-slice basis, which means that four consecutive slices are put in one bank, then the next four slices are put in the other bank and so on. This four-slice scheme was chosen to make block mode operations easier.

For example, at the beginning of the frame buffer in 32 bits/pixel, the pixels are arranged as follows between the two banks:

**Figure 6-3: Pixel Arrangement**

For fbm = 4 and 6, Banks A and B are assigned as follows:

<i>Address</i> <i>(Bytes)</i>	<i>Bank</i>	
	<i>A</i>	<i>B</i>
00000h-3FFFFFFh	2	3

For fbm = 5 and 7, Banks A and B are assigned as follows:

<i>Address</i> <i>(Bytes)</i>	<i>Bank</i>	
	<i>A</i>	<i>B</i>
00000h-1FFFFFFh	2	4
20000h-3FFFFFFh	2	3
40000h-5FFFFFFh	4	3

### 6.3.2 Patch RAM

The patch RAM is an optional device. Since for fbm = 01XX only 24(32) bits/pixel are supported, there's no need to populate the complete 64 bit data bus. However, offscreen memory can be used for font caching, patterns, and so on. Since the offscreen area accesses must be 64 bits, and the unused display bits are not contiguous, the patch RAM 'patches up the gaps' to support 64-bit data in the offscreen memory while the display area is only populated for 24 bits/pixel.

Since the patch RAM isn't used for video, normal DRAM can be used. Refer to Section 3.2.1 'Memory Configurations' for more information about where the patch RAM is mapped.

If Banks 2, 3 and 4 are fully populated, the patch RAM can't be used. Also, if DRAM is added to the system, the patch RAM may not be required, since some offscreen space will be available.

### 6.3.3 ZTAG RAM

ZTAG RAM is another optional device. The purpose of the ZTAG is to accelerate clearing of the depth buffer during animation. Since the depth buffer can be implemented in DRAM, and the ZTAG is in VRAM, the ZTAG can be cleared four times faster than the DRAM (using block mode).

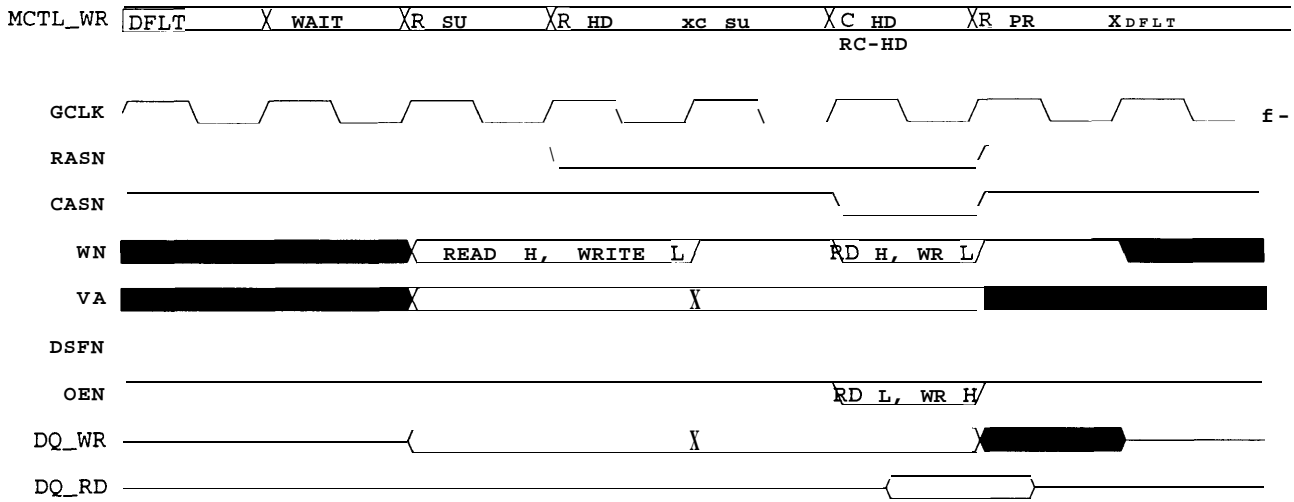

Here are the principles of ZTAG use:

- . A bit is assigned in ZTAG for each pixel in the Z buffer
  - The ZTAG bit indicates whether or not the value in the Z buffer is valid
  - The ZTAG is cleared (rather than the depth buffer)
- . Each time a pixel is updated, the ZTAG is set
- . When the Z buffer is invalid, depth comparison is done by means of an internal background depth value.

Since the ZTAG uses a separate pin on the ATHENA chip, it can be updated in parallel with the frame buffer when 16 bits/pixel is selected. The ZTAG is optional, since it can be disabled in ATHENA.

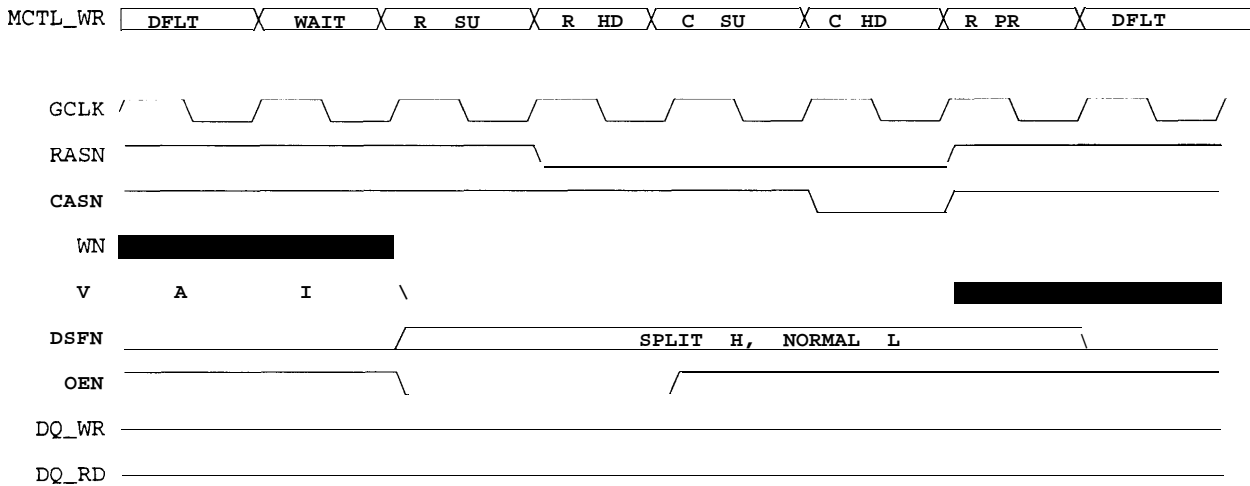

### 6.3.4 MCTLWTST Register Timings

The MCTLWTST (Memory Control Wait State) register is described in detail in Chapter 5. The following figures show the various cycles that are generated by the drawing engine. At the top of each timing diagram, the field of MCTLWTST that specifies the length of this state is shown.

**Figure 6-4: MCTLWTST for Direct Access Cycle**

- :a During a direct read access, a state is added between RC-HD and R\_PR, using the MCTLWTST wait field. This state has the same effect as the R\_PR field on VRAM signals.

**Figure 6-5: MCTLWTST for Data Transfer Cycle**

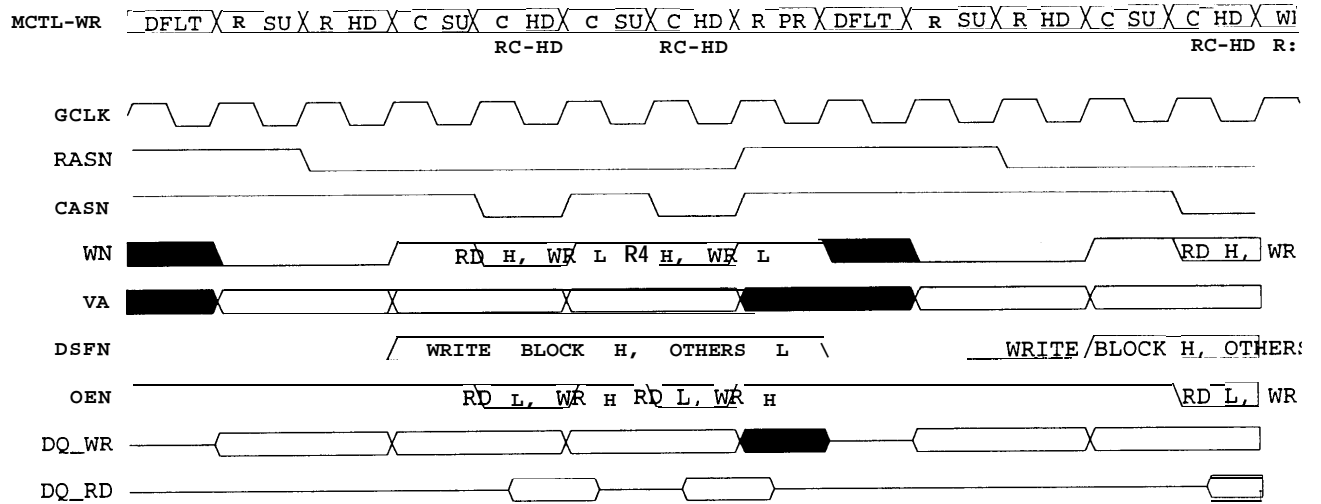

Figure 6-6: MCTLWTST for Page Write and Page Read Cycle

Figure 6-7: MCTLWTST for Refresh Cycle

### 6.3.5 VRAM Interconnect

Two operation modes are supported (No DUBIC mode, and DUBIC mode).

In DUBIC mode, the ATHENA chip works in conjunction with the MGA DUBIC chip to control the VRAM and RAMDAC. All memory configurations are supported. This mode offers more flexibility, but is slightly less economical due to the requirement of the DUBIC chip.

In No DUBIC mode, the ATHENA chip directly controls the VRAM and RAMDAC, so there is no need for a DUBIC chip. Note that only Banks 0 to 3 can be populated. While this mode permits a smaller number of configurations, the possibility of memory conflict is reduced.

In both cases, the random port of the VRAM is interconnected the same way. The only difference is that since No DUBIC supports a smaller number of configurations, less control signals are available. In No DUBIC mode, only RAS<1:0>/, CAS<1:0>/, and OE<1:0>/ are generated by ATHENA.

**VAA<13:0>** The address connection between the ATHENA and the VRAM depends on the Bank, the fbm, and the location of the VGA. The following tables show the different possibilities. Whenever possible, it would be preferable to attempt to distribute the load evenly between every address (if 16 memory chips require Bit 6 of the VAA and VAB buses, attach eight bits to VAA<6> and eight bits to VAB<6> to equalize the load).

- Legend:**
- \*1 When 'Y', the VGA frame buffer is implemented in this bank. When 'N', the VGA frame buffer is not implemented in this bank.
  - \*2 For all addresses, 'A' indicates a signal on the VAA bus, 'B' indicates a signal on the VAB bus, and *no letter indicates a signal on either bus.*
  - \*3 For Banks 0 to 4, address ordering is very important and should be respected. For Banks 5, 7, and 8, address ordering can be changed, except for the addresses which are not used at column time. For Bank 6, address ordering can be changed, except for Addresses 0 and 1.

**Example:** The following table indicates, for example, that to access Bank 2 with fbm = 0010 and no VGA frame buffer, memory address 7 can connect to ATHENA address 7 (VAA bus), or 12 (VAA bus), or 8 (VAA bus). Memory address 6 can only connect to ATHENA address 6 (VAA or VAB bus).

**Table 6-3: ATHENA/VRAM Address Connection**

**RAS<4:0>/** RAS/ strobe. Used for bank selection. Five different RAS/ strobes (two strobes in No DUBIC mode) are generated by ATHENA. The following table shows how ATHENA's RAS/ strobes are mapped to VRAM chips for each memory configuration.

<i>fbm</i>	<i>RAS</i>								
	<i>8</i>	<i>7</i>	<i>6</i>	<i>5</i>	<i>4</i>	<i>3</i>	<i>2</i>	<i>1</i>	<i>0</i>
0000			4	2				1	0
0001			4	2				1	0
0010			4	2		0	1		
0100		4	4	2		0	1		
0101		4	4	2	3	0	1		
0110	4		4	2		<b>0</b>	1		
0111	4		4	2	3	0	1		
1010			4	2		0	1		

**Table 6-4: RAS Assignment**

For example: to access Bank 4 with *fbm* = 0101, you must use **RAS<3>/**.

**CAS<4:0>/** CAS/ strobe. Used for final bank selection during write cycles. There are five different CAS/ strobes (two strobes in No DUBIC mode) generated by ATHENA. The table below shows how ATHENA's CAS/ signals are mapped to VRAM chips for each memory configuration.

**OE<4:0>/** DT/OE strobe. Used for final bank selection during read cycles. There are five different DT/ strobes (two strobes in No DUBIC mode) generated by the ATHENA. The table below shows how the DT/ signals generated by ATHENA are mapped to VRAM chips for each memory configuration.

<i>fbm</i>	<i>CAS/ or OE/</i>								
	<i>8</i>	<i>7</i>	<i>6</i>	<i>5</i>	<i>4</i>	<i>3</i>	<i>2</i>	<i>1</i>	<i>0</i>
0000			2	2				1	0
0001			2	2				1	0
0010			2	2		0	1		
0100		4	2	2		0	<b>1</b>		
0101		4	2	2	3	0	1		
0110	4		2	2		0	1		
0111	4		2	2	3	0	1		
1010			2	2		0	1		

**Table 6-5: CAS and OE Assignment**

**WT<7:0>/** Write strobe. The Write strobes are used for pixel selection. Because the minimum pixel size is 8 bits/pixel, there is one strobe per byte.

**DSF<1:0>** Special function pin of the VRAM. This pin permits different types of data transfer (split – normal) simultaneously in different banks.

<i>fbm</i>	<i>DSF</i>								
	8	7	6	5	4	3	2	1	0
0000			X					x	x
0001			X					x	x
0010			X			x	x		
0100			X			x	x		
0101			X		0	1	0		
0110			X			x	x		
0111			X		0	1	0		
1010			X			x	x		

X = 'don't care'

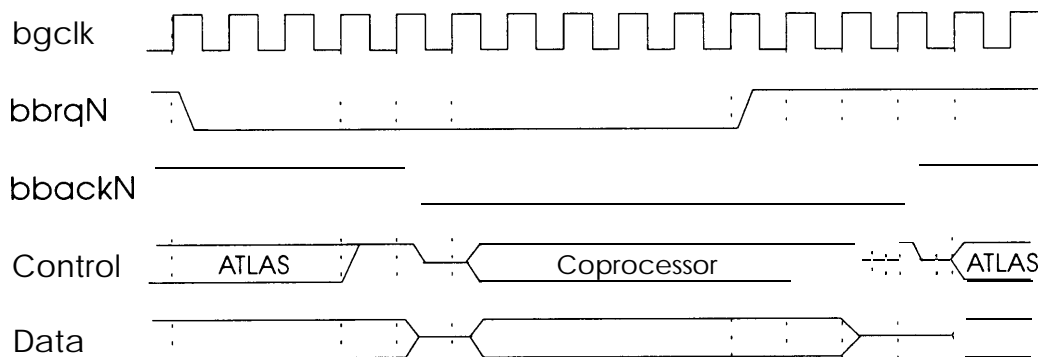

**Table 6-6: DSF Assignment**

### 6.3.6 Coprocessor Requests

Two pins permit sharing of the VRAM bus: **BACK/** (generated by ATHENA) and **BRQ/** (generated by the coprocessor). This handshaking can be synchronous or asynchronous on **GCLK**.

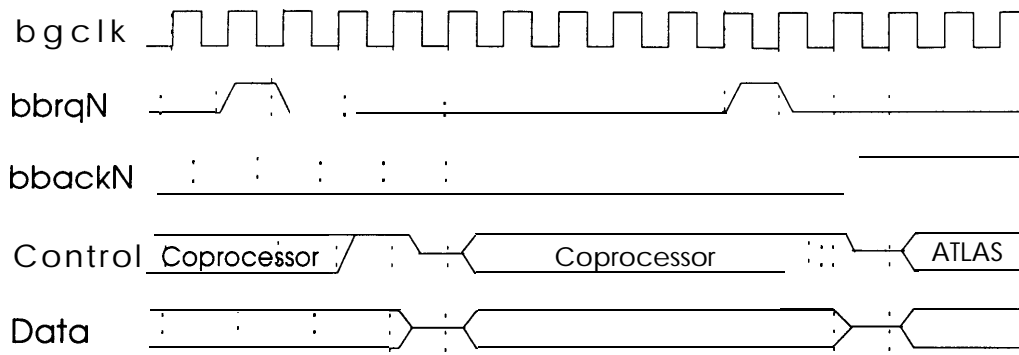

When it releases the bus to the coprocessor, the ATHENA chip brings all VRAM control signals high before putting them in tri-state. The coprocessor should do the same thing when releasing the bus. This procedure guarantees that no false access will be performed on the memory.

Figure 6-10 shows the normal sequence when the coprocessor requests and releases the bus.

**Figure 6-10: Normal Request and Release of the Bus**

In order to allow the ATHENA chip to perform refresh cycles, the coprocessor must release the bus every 10 μS, for a minimum of one clock cycle. When the coprocessor releases the bus for only one clock cycle, ATHENA processes only the high priority refresh cycle. This is shown in Figure 6-11. Since the co-processor must generate a pulse of 1 GCLK on **BRQ/**, this cycle can only be used with a co-processor that generates a synchronous handshake. If this is not the case, the co-processor must release the bus every 10 μs for refresh, or else perform refresh on the VRAM.

**Figure 6-11: 1 gclk Release for Refresh**

Finally, the ATHENA chip will notify the coprocessor that it requires the bus for a data transfer by removing the BACK/ signal. In this case, the coprocessor has a maximum of 20 clock cycles within which it must return the bus to the ATHENA. This is shown in Figure 6-1 2.

**Figure 6-12: ATHENA Request for Data Transfer**

## 6.4 VIDEO Interface

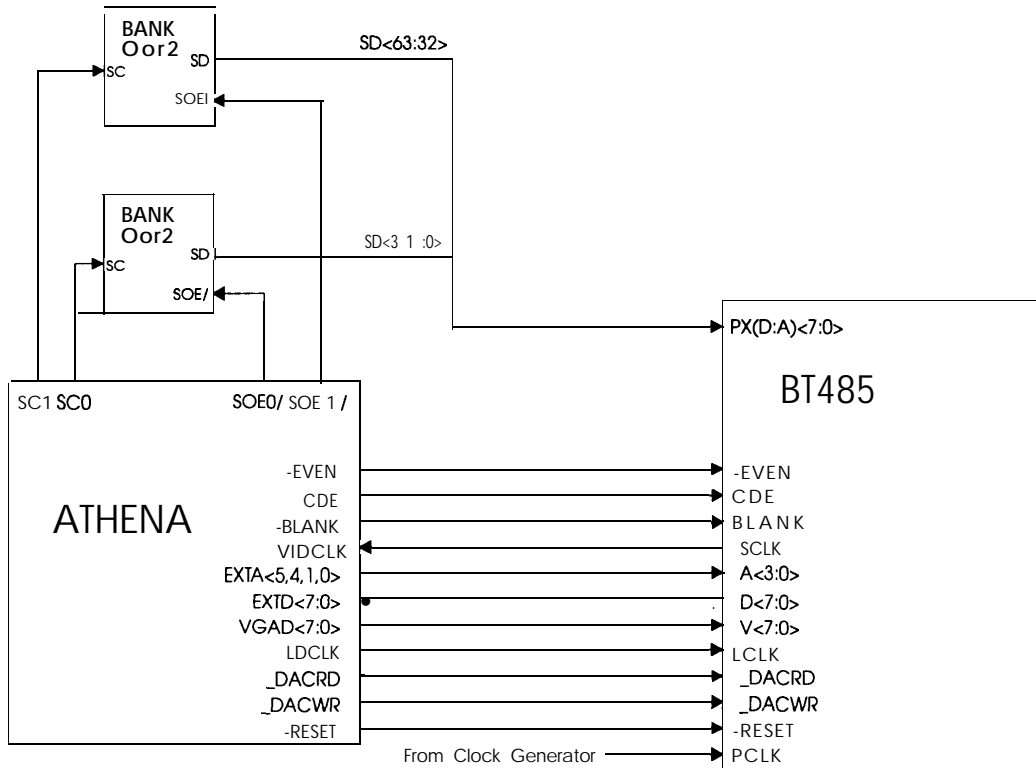

The video interface is different for Power Graphic mode and VGA mode. As well, Power Graphic mode supports the following two configurations: No DUBIC mode and DUBIC mode.

### 6.4.1 Power Graphic Mode (No DUBIC Mode)

In 'No DUBIC' mode, ATHENA itself is responsible for generating all the control signals for the VRAM serial port and RAMDACs. There are three possible configurations.

- No mux: This configuration uses the output enable pins of the VRAM to multiplex the video data to a 32-bit bus. This is shown in Figure 6-13.
- 32-bit RAMDAC: This configuration is compatible with MGA ATLAS chip, and requires multiplexers to generate the video data to the RAMDAC. This is illustrated in Figure 6-14.
- 64-bit RAMDAC: This configuration is compatible with the MGA ATLAS chip, and uses a 64-bit RAMDAC (such as the TI VIEWPOINT). In this case, no external multiplexers are required, since the RAMDAC's pixel port size matches that of the external memory interface. This is shown in Figure 6- 15.

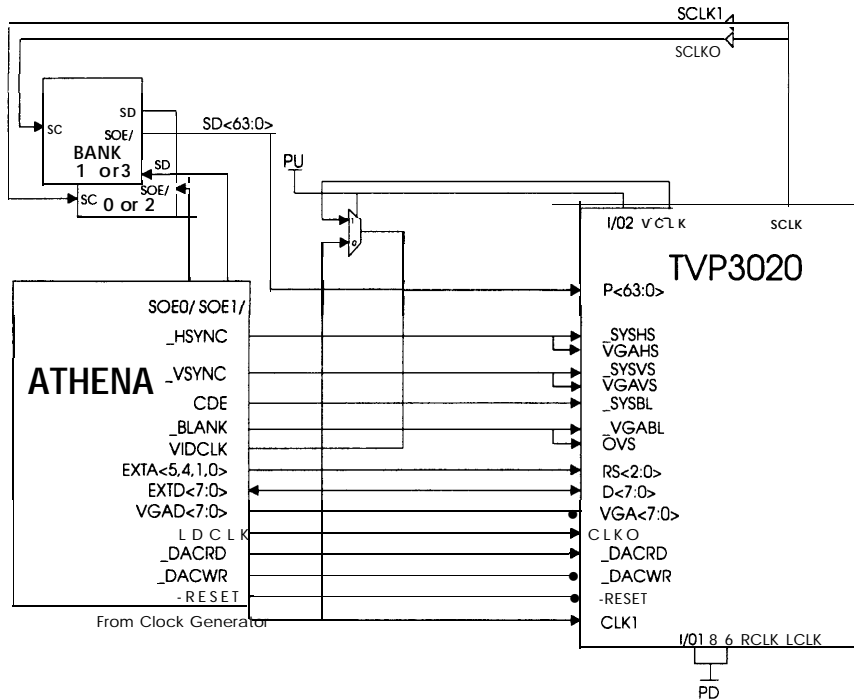

**Figure 6-13: ATHENA/Memory Connection 32 Bit No MUX**

**Figure 6-14: ATHENA/Memory Connection to 32 Bit RAMDAC**

**Figure 6-15: ATHENA/Memory Connection to 64 Bit RAMDAC**

#### 6.4.2 Power Graphic Mode (DUBIC Mode)

In Power Graphic mode when a DUBIC chip is present ('DUBIC mode'), controls are generated that cause the DUBIC chip to generate serial clocks to the VRAM as well as blank and sync signals for the video output.

In this mode, only the VIDINF pins are used for video generation.

<b>VIDINF&lt;3:0&gt;</b>	<b>Code Description</b>
<b>0000</b>	Horizontal and vertical sync and blank
0001	Horizontal sync and blank
0010	Vertical sync and blank
0011	Blank
0100	Display border color
0101	Active video
0110	Bank switching
0111	Vertical sync and blank (field 1)
1000	Data transfer in the current bank
1001	Bank switching and data transfer in the next bank
1110	Backward bank switch

**Table 6-7: Power Graphic Mode Video Generation**

Refer to the *DUBIC Specification* for more information on interconnecting the VRAM serial port, RAMDAC, DUBIC, and ATHENA.

### 6.4.3 VGA Mode

In VGA mode, ATHENA outputs different video signals, according to whether or not the system is operating in No DUBIC mode or in DUBIC mode. Refer to Table 6-8 for the signal assignment.

<i>Signal Description</i>	<i>No DUBIC Mode</i>	<i>DUBIC Mode</i>
Pixel clock	LDCLK	VIDINF<3>
Blanking signal	BLANK/	VIDINF<2>
Horizontal sync signal	HSYNC/	VIDINF<1>
Vertical sync signal	VSYNC/	VIDINF<0>
VGA data <7>	VAA<11>	VAA<11>
VGA data <6>	VGAD<6>	OE<2>/
VGA data <5>	VGAD<5>	OE<4>/
VGA data <4>	VGAD<4>	OE<3>/
VGA data <3>	VGAD<3>	ZTAG<3>
VGA data <2>	VGAD<2>	ZTAG<2>
VGA data <1>	VGAD<1>	ZTAG<1>
VGA data <0>	VGAD<0>	ZTAG<0>

**Table 6-8: VGA Signal Assignment**

### 6.4.4 Slaving ATHENA

The VIDRSTN input pin of the chip is used to synchronize the MGA video with other external video sources.

Inside the CRTC circuitry, there are two ‘total compare’ signals (one for the horizontal counter, and one for the vertical counter). These signals reset the corresponding horizontal or vertical counter, based on the total values programmed in the registers.

Like the total compare signals, the VIDRSTN signal resets the horizontal and vertical counters. In other words, the VIDRSTN signal is responsible for initially synchronizing the video circuitry when it is necessary to get in phase with another video source. Two bits in the CRTC\_CRTL register are used to enable the reset of either or both of the counters.

The VIDRSTN signal is periodic and must have exactly the same period as that obtained by the programmed video parameters. The period of VIDRSTN is either the same as the period of one line, or the same as the period of one frame (depending on the kind of synchronization that is necessary).

The first application of the signal will create a momentary instability in the video signals (blank, syncs, etc.). After this, the CRTC counters will be in phase with the VIDRSTN signal, and video signal generation will become stable.

When the vertical reset is used, the VIDRSTN signal is maintained internally until the next vertical clock (which is the horizontal retrace ~ this is also when the vertical counter is reset). It is necessary to send a VIDRSTN pulse of only one clock in length, once per frame (even in vertical reset).

In VGA mode, the VIDRST signal must be maintained active for a minimum of 8 VIDCLKs. In Power Graphic mode, VIDCLK is always divided by 8, so VIDRST can be maintained for only one VIDCLK.

The following figures illustrate the video signal waveforms and counters in relation to the video reset input signal once the CRTC is in phase with the video reset signal (VIDRSTN). The counter numbers are provided as sample values for a resolution of 1024 x 768.

**Figure 6-16: Horizontal Video Reset (eg. 1024x768)**

**Figure 6-17: Vertical Video Reset (eg. 1024x768)**

---

## ***Appendix A: Technical Data***

***T***his appendix contains the electronic and mechanical technical information for the Matrox MGA ATHENA chip, including the pin list and timing information.

## A.1 Pin List

When groups of pins are listed together, they're presented in order from MSB to LSB.

### A.1.1 Host Interface (ISA Configuration)

<i>Name</i>	<i>No. of pins</i>	<i>Type</i>	<i>Description</i>
A<23:16>	8	I/O	Partial Address bus. Not multiplexed. Pins: 10 17 29 48 97 143 144 175
A<7:0>	8	I/O	Partial Address bus. Not multiplexed. Pins: 162 153 127 126 125 124 123 113
AD<15:8>	8	I/O	Address and Data multiplexed bus. Pins: 152 134 133 112 111 103 102 98
D<7:0>	8	I/O	Partial Data bus. Not multiplexed. Pins: 74 58 57 49 38 30 19 18
HADREN/	1	0	Host <b>AD</b> dRess <b>EN</b> able. External address buffer enable. Pin: 96
HDATAEN<1:0>/	2	0	Host <b>DATA</b> byte <b>EN</b> able bus. External data buffer enable signals. Pins: 142 70
HWRDIR	1	0	Host <b>WR</b> ite <b>DIR</b> ection. External data buffer direction control signal. Pin: 158
AEN	1	I	Address <b>EN</b> able signal. Prevents IO decodes during DMA cycles. Pin: 55
MCS16/	1	0	Memory Chip Select 16 signal. Pin: 90
CHRDY	1	0	<b>ReaDY</b> signal. Pin: 116
CHRDYEN/	1	0	This pin can be used to enable an external <b>CHRDY</b> buffer so that the bus ready signal is driven high before being disabled. Pin: 105
REFRESH/	1	I	<b>REFRESH</b> cycle signal. Prevents memory decodes during bus refresh cycles. Pin: 86
MRDC/	1	I	Memory <b>ReaD</b> Control strobe. Pin: 82
MWTC/	1	I	Memory <b>WriTe</b> Control strobe. Pin: 84

<b>Name</b>	<b>No. of pins</b>	<b>Type</b>	<b>Description</b>
IORC/	1	I	I/O Read Control strobe. Pin: 91
IOWC/	1	I	I/O Write Control strobe. Pin: 106
BALE	1	I	Bus Address Latch Enable signal. Pin: 69
SBHE/	1	I	System Bus High Enable signal. Pin: 99
IRQ	1	0	Interrupt ReQuest signal. - The same interrupt is used for ATHENA and VGA. - A shared interrupt protocol is used in Power Graphic mode, but not in VGA mode. - There is a rising edge trigger (ISA type) interrupt in VGA mode. - There is a negative level interrupt option in Power Graphic mode. - Open collector output. Pin: 171
NMI/	1	0	Generate an NMI to the host CPU for CGA-Hercules CRTC register emulation. This pin is connected to the IOCHW pin on ISA. It is useful only if the ATHENA VGA is used. Pin: 83
DECODE< 1 :0>/	2	I	Optional high level DECODE pins which should be pulled down when not used. Refer to the map table in the CONFIG register description in Chapter 5 (page 5-52) for more information. Pins: 73 72
ISA	1	0	Indicates that the ATHENA is operating in the ISA configuration and not in the PCI configuration. Pin: 56
DRQ	1	0	DMA ReQuest signal. Refer to Section 3.2.4 for more information. Pin: 104
DAK/	1	I	DMA AcKnowledge signal. Refer to Section 3.2.4 for more information. Pin: 157
TC	1	I	Terminal Count signal. Refer to Section 3.2.4 for more information. Pin: 118
PU	2	I	Connected to a pull-up. Pins: 107 115
NC	2	0	No Connect signals. Pins: 114 156

## A.1.2 Host Interface (PCI Configuration)

<i>Name</i>	<i>No of pins</i>	<i>Type</i>	<i>Description</i>
PCLK	1	I	This CLoCK provides timing for all transactions on PCI. Pin: 86
PCBE<3:0>/	4	I	PCI Bus Command and Bytes Enables are multiplexed on the same PCI pins. During the address phase of a transaction, PCICBE<3:0> defines the bus command. During the data phase, the PCICBE<3:0> signals are used as byte enables. Pins: 156 114 142 70
PAD<31:0>	32	I/O	Address and Data multiplexed bus. During the first clock of a transaction PCIAD<31:0> contains a physical address; during subsequent clocks PCIAD<31:0> contains data. Pins: 10 17 29 48 97 143 144 175 162 153 127 126 125 124 123 113 152 134 133 112 111 103 102 98 74 58 57 49 38 30 19 18
PPAR	1	0	PARity is even across PCIAD<31:0> and PCICBE<3:0>. Parity is generated during read data phases. Pin: 83
PFRAME/	1	I	Cycle FRAME indicates the beginning and duration of an access. Pin: 96
PTRDY/	1	0	Target ReaDY indicates the ATHENA chip's ability to complete the current data phase of the transaction. It is used in conjunction with IRDY/. Wait cycles are inserted until both IRDY/ and TRDY/ are asserted together. Pin: 82
PIRDY/	1	I	Initiator ReaDY indicates the initiating agent's ability to complete the current data phase of the transaction. It is used in conjunction with TRDY/. Wait cycles are inserted until both IRDY/ and TRDY/ are asserted together. Pin: 116
PDEVSEL/	1	0	DEViCESElect, when actively driven, indicates that the ATHENA chip has decoded its address as the target of the current access. Pin: 84
PSTOP/	1	0	STOP indicates that ATHENA is requesting that the master device halt the current transaction. Pin: 91

PINTA	1	0	<b>INTerrupt ReQuest</b> signal. - The same interrupt is used for ATHENA and VGA. - A shared interrupt protocol is used in Power Graphic mode, but not in VGA mode. - There is a rising edge trigger (ISA type) interrupt in VGA mode. - There is a negative level interrupt option in Power Graphic mode. - Open collector output. Pin: 171
PIDSEL	1	I	Initialization Device <b>SE</b> lect is used as a chip select in lieu of the upper 24 address lines during configuration read and write transactions. Pin: 105

### A.1.3 External Device Interface (ISA Configuration)

<i>Name</i>	<i>No. of pins</i>	<i>Type</i>	<i>Description</i>
DACRD/	1	0	ramDACReaD control strobe. Pin: 138
DACWR/	1	0	ramDACWRite control strobe. Pin: 137
ROMEN/	1	0	BIOS ROM ENable strobe. Pin: 117
DEVWR/	1	0	external DEViCe WRite. This pin indicates if the current external device cycle is a read (1) or a write (0). Pin: 109
DUBICSL/	1	0	DUBIC SeLect strobe. This pin works in conjunction with the DEVWR/ signal. Pin: 154
VIWICSL/	1	0	VIWIC SeLect strobe. This pin works in conjunction with the DEVWR/ signal. Pin: 155
EXPSL/	1	0	EXPansion SeLect control strobe. This pin can be used as the VGA expansion write signal or for other expansion devices when EXPDEV/ is active. In this case, external decoding circuitry is required. Pin: 141
CLKGEN<1:0>	2	0	Clock generator control bits. These bits come from the VGA Miscellaneous Output Register 3C2<3:2>. Pins: 129 128

## A.1.4 External Device Interface (PCI Configuration)

<b>Name</b>	<b>No of pins</b>	<b>Type</b>	<b>Description</b>
EXTA<6:0>	7	0	EXTernal device Addresses. If external devices are enabled, the EXTA<3:2> bits are used as second and first decoder addresses, and EXTA<6> is used as a R/W signal. Pins: 158 157 118 69 154 155 141
EXTD<7:0>	8	I/O	EXTemal Device data bus. This bus is also used as EXTA<14:7> for EPROM accesses. Pins: 115 56 104 107 99 55 73 72
ROMEN/	1	0	BIOS ROM output ENable signal. This pin is also used as the chip select by the external decoder for other external devices. Pin: 117
EIRQ/	1	I	External device Interrupt ReQuest. Pin: 90
DACRD/	1	0	RAMDAC ReaD control signal. If external devices are enabled, this bit is used as the decoder enable strobe. Pin: 138
DACWR/	1	0	RAMDAC WRite control signal. If external devices are enabled, this bit is used as the third decoder address. Pin: 137
CLKGEN< 1:0>	2	0	CLoCK GENerator control bits which emanate from the VGA Miscellaneous Output register (3C2<3:2>). Pins: 129 128
EXTALEN	1	0	EXTernal Address Latch. This pin is used to latch the MSB addresses in an external latch when an EPROM access is performed. This pin is also used as a chip select on the EPROM, and as a positive chip select by the external decoder for other external devices. Pin: 106
DEVRST/	1	0	DEVIce ReSeT. Reset output generated for local devices. Pin: 109

## A.1.5 Drawing Engine (No DUBIC Mode)

<b>Name</b>	<b>No of pins</b>	<b>Type</b>	<b>Description</b>
VD<63:0>	64	I/O	Video Data bus. These pins are connected to VRAM and DRAM. Pins: 131 136 147 148 149 165 166 167 168 176 177 178 182 183 184 185 195 196 197 203 204 205 206 212 213 214 215 216 224 225 226 232 233 234 235 236 237 8 9 14 15 16 25 26 27 28 34 35 36 37 42 43 44 53 54 62 63 64 65 75 76 77 87 93
VAA<13:0>	14	0	VRAM and DRAM multiplexed addresses. This bus includes all of the different addresses that must be generated for all banks of VRAM and DRAM. Refer to Table 6-3 for more information. Pins: 146 164 186 187 188 198 189 199 217 218 3 23 33 94
VAB<6:0>	7	0	VRAM and DRAM multiplexed addresses. This bus includes all the addresses that are the same for Power Graphic mode (duplicated for load distribution) but different in VGA mode (for character modes). Refer to Table 6-3 for more information. Pins: 207 208 227 231 22 32 78
RAS<1:0>/	2	0	RAS/ strobe, used for bank selection. Five different RAS/ strobes are generated by ATHENA. Refer to Table 6-4 for more information. Pins: 238 239
CAS<1:0>/	2	0	CAS/ strobe, used for final bank selection during write cycles. Five different CAS/ strobes are generated by ATHENA. Refer to Table 6-5 for more information. Pins: 12 39
OE<1:0>/	2	0	DT/OE strobe, used for final bank selection during read cycles. Five different DT/ strobes are generated by ATHENA. Refer to Table 6-5 for more information. Pins: 163 173
WT<7:0>/	8	0	WriTe strobes, used for pixel selection. Because the minimum pixel depth is 8 bits/pixel, there is one strobe per byte. The ninth strobe is unused. Pins: 174 209 219 13 45 46 51 52
DSF<1:0>	2	0	Special Function pin of the VRAM. This pin permits different types of data transfer (split/normal) simultaneously in different banks. Refer to Table 6-6 for more information. Pins: 68 135
BRQ/	1	I	Co-processor VRAM Bus ReQuest. Pin: 6
BACK/	1	0	ACKnowledge from ATHENA of the VRAM bus request. Pin: 7

## A.I.6 Drawing Engine (DUBIC Mode)

<b>Name</b>	<b>No. of pins</b>	<b>Type</b>	<b>Description</b>
VD<63:0>	64	<b>I/O</b>	Video Data bus. These pins are connected to VRAM and DRAM. Pins: 131 136 147 148 149 165 166 167 168 176 177 178 182 183 184 185 195 196 197 203 204 205 206 212 213 214 215 216 224 225 226 232 233 234 235 236 237 8 9 14 15 16 25 26 27 28 34 35 36 37 42 43 44 53 54 62 63 64 65 75 76 77 87 93
ZTAG<3:0>	4	<b>I/O</b>	Video data bus. These pins are connected to the ZTAG RAM (Bank 6). Pins: 24 66 79 95
VAA<13:0>	14	<b>0</b>	VRAM and DRAM multiplexed Addresses. This bus includes all the addresses that must be generated for all banks of VRAM and DRAM. Refer to Table 6-3 for more information. Pins: 146 164 186 187 188 198 189 199 217 218 3 23 33 94
VAB<6:0>	7	<b>0</b>	VRAM and DRAM multiplexed Addresses. This bus includes all the addresses that are the same for Power Graphic mode (duplicated for load distribution) but are different in VGA mode (for character mode). Refer to Table 6-3 for more information. Pins: 207 208 227 231 22 32 78
RAS<4:0>/	5	<b>0</b>	RAS/ strobe. Used for bank selection. There are five different RAS/ strobes generated by ATHENA. Refer to Table 6-4 for more details. Pins: 47 222 223 238 239
CAS<4:0>/	5	<b>0</b>	CAS/ strobe. Used for final bank selection during write cycles. There are five different CAS/ strobes generated by ATHENA. Refer to Table 6-5 for more information. Pins: 88 202 4 12 39
OE<4:0>/	5	<b>0</b>	DT/OE strobe. Used for final bank selection during read cycles. There are five different DT/ strobes generated by ATHENA. Refer to Table 6-5 for more information. Pins: 89 145 194 163 173
WT<7:0>/	9	<b>0</b>	WriTe strobe. Write strobes are used for pixel selection. Because the minimum pixel size is 8 bits/pixel, there is one strobe per byte. The ninth strobe is unused. Pins: 174 209 219 13 45 46 51 52
DSF<1:0>	2	<b>0</b>	Special Function pin of the VRAM. This pin permits different types of data transfer (split - normal) simultaneously in different banks. Refer to Table 6-6 for more information. Pins: 68 135

BRQ/	1	I	Co-processor VRAM Bus ReQuest. Pin: 6
BACK/	1	0	ACKnowledge from the ATHENA of the VRAM bus request. Pin: 7
NC	1	I/O	Not Connected. Pin: 67

### A.1.7 Video Interface (No DUBIC Mode)

<i>Name</i>	<i>No of pins</i>	<i>Type</i>	<i>Description</i>
VIDCLK	1	I	Input CLoCK for the CRTIC and the DT request module in Power Graphic mode. Pin: 229
VIDRST/	1	I	VIDeo ReSeT input. Pin: 159
HSYNC/	1	0	Horizontal SYNC. In VGA mode, sync polarity is selected from the VGA control register. In Power Graphic mode, the sync is always active low. Pin: 211
VSYNC/	1	0	Vertical SYNC. In VGA mode, sync polarity is selected from the VGA control register. In Power Graphic mode, the sync is always active low. Pin: 169
BLANK/	1	0	Video BLANK signal. Pin: 193
CDE	1	0	Video CDE signal. Pin: 223
LDCLK	1	0	Video CLoCK. Pin: 191
VGAD<6:0>	7	0	VGA Data output. VGAD<7> is multiplexed with VAA<11>. Pins: 194 89 145 24 66 79 95
SC<1:0>	2	0	Serial Clock. Each half-bank is connected to one of these serial clock pins. Pins: 88 202
SOE<1:0>/	2	0	Serial Output Enable control for each bank. Pins: 47 222
EVEN/	1	0	EVEN line signal (used for interlace operation only). The even field is defined as the field that starts with line two, while the odd field starts with line one. Pin: 67
SMUXSL	1	0	Serial MUX Low input select. This pin connects directly to the select pin of the muxes. Pin: 4

## A.1.8 Video Interface (DUBIC Mode)

<b>Name</b>	<b>No. of pins</b>	<b>Type</b>	<b>Description</b>
VIDCLK	1	I	Input CLoCK for the CRTc and the DT request module in Power Graphic mode. Pin: 229
VIDRST/	1	I	VIDeo ReSeT input. Pin: 159
VIDINF<3:0>	4	0	VIDeo INFormation (to DUBIC). Refer to Table 6-7 for more information. Not available in No DUBIC mode. Pins: 191 193 211 169

## A.1.9 Miscellaneous

### A.1.9.1 Fixed

<b>Name</b>	<b>No. of pins</b>	<b>Type</b>	<b>Description</b>
GCLK	1	I	Graphic (and host interface) CLoCK. Pin: 151
RESET/	1	I	This is an active low hard RESET pin. Pin: 119

### A.1.9.2 Test

<b>Name</b>	<b>No. of pins</b>	<b>Type</b>	<b>Description</b>
HIZ	1	I	This pin is used to put all bi-directional buffers in tri-state. This pin should be tied to a pull-down resistor on all products. Pin: 108
PD	1	I	Connected to a pull-down. Pin: 5
<NANDTREE>	1	0	Output of the NAND TREE. This is a shared pin. Pin: 109
<RINGOSC>	1	0	Output of the RING OSCillator (the ring oscillator is enabled when the chip is in reset). This is a shared pin. Pin: 158

### A.1.9.3 VCC/GND

<b>Name</b>	<b>No of pins</b>	<b>Type</b>	<b>Description</b>
<b>PWR</b>	16		Attached to <b>+5</b> Volts.
			Pins: 21 40 61 81 100 120 132 140 160 172 181 190 201 220 228 240
<b>GND</b>	29		Attached to <b>GrouND</b> .
			Pins: 1 2 11 20 31 41 50 59
			60 71 80 85 92 101 110 121
			122 130 139 150 161 170 179 180 192 200 210 221 230

## A.2 Electrical Specification

### A.2.1 Maximum Ratings

- Storage Temperature: -40° C. to +125° C.
- DC Supply Voltage: -0.5 V to +7.0 V
- I/O pin voltage with respect to VSS: -0.5 V to VDD + 0.5 V

### A.2.2 DC Specifications

. For VDD = 5.0 +- 5% , Ta = 0 to 55° C.

Symbol	Parameter	Conditions	Min.	Typical	Maximum	Units
VIL	Input low voltage				0.8	V
V I H	Input high voltage		2.2			V
VOL	Output low voltage I=IOL				0.4	V
		IOL=0			0.1	V
VOH	Output high voltage I=IOH		2.4			V
		IOH=0	V <sub>DD</sub> -0.1			V
VT	Switching Threshold	Schmidt buffer (SC) Positive going	1.2		2.4	V
		Schmidt buffer (SC) Negative going	0.6		1.8	V
IIL	Input low current		-10			μA
		With pull up (PU)	-40	-100	-270	μA
IIH	Input high current				10	μA
		With pull down (PD)	40	100	270	μA
ICC	Power supply current				480	mA
IOL	Output low current	Applies to signals with 4 mA drivers			4	mA
		Applies to signals with 6 mA drivers			6	mA
		Applies to signals with 8 mA drivers			8	mA
		Applies to signals with 12 mA drivers			12	mA
		Applies to signals with PCI buffers			24	mA
IOH	Output high current	Applies to signals with 4 mA drivers			-2	mA
		Applies to signals with 6 mA drivers			-3	mA
		Applies to signals with 8 mA drivers			-4	mA
		Applies to signals with 12 mA drivers			-6	mA
		Applies to signals with PCI buffers			-12	mA
IOZ	Output tri-state current				10	μA
C	Pin capacitance		10		20	pF

Tde164	14*gclk		irq LOW → irq HIGH	(3)(11)(19)
Tpd65		3*gclk+35	mwtc/ HIGH → isa	(3)(19)
Ta66	1 μs		reset ACTIVE	(3)(12)(19)

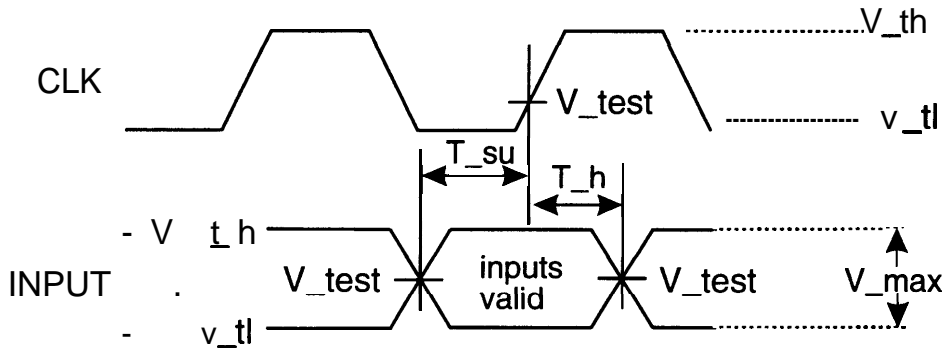

**Table A-11: Host Interface Parameter List**

Notes:

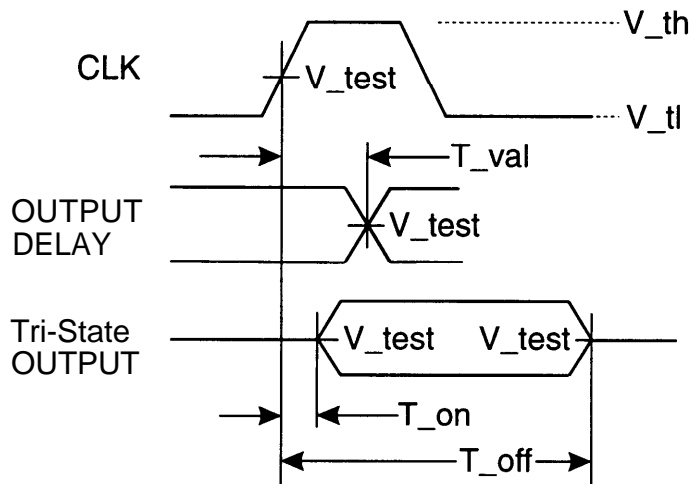

- (1) ISA timing
- (2) DMA timing
- (3) The timing appears only as a note, and isn't shown in the diagram.
- (4) Necessary only for cycles in which there is no BALE.
- (5) VGA I/O read.
- (6) VGA I/O write.
- (7) VGA frame buffer read.
- (8) VGA frame buffer write.
- (9) After a CONFIG or OPMODE register write.
- (10) Narrow decode only.
- (11) Edge-triggered interrupt mode.
- (12) The timing is also a function of the pull-up or pull-down, and the load.
- (13) Write cycle.
- (14) Read cycle.
- (15) Must be considered only when hadren/ and hdataen/ are used.

- (16) Can be ignored if **hadren/** and **hdataen/** are used, since an equivalent timing is guaranteed (as long as external buffers respect the constraints mentioned in Section 6.2.1.4).
- (17) Write cycles without wait states.
- (18) Use the upper expression if  $gclk < 25$ . For other  $gclk$  values use the lower expression.
- (19) These timings are not shown in the corresponding waveform.

**Timing Conditions**

**Figure A-2: Host PCI Input Waveform**

**Figure A-3: Host PCI Output Waveform**

Figures A-2 and A-3 define the conditions under which timing measurements are made. The component test guarantees that all timings are met with minimum clock slew rate (slowest edge) and voltage swing. The design guarantees that minimum timings are also met with maximum clock slew rate (fastest edge) and voltage swing. The design also guarantees proper input operation for input voltage swings and slew rates that exceed the specified timing conditions.

<b>Symbol</b>	<b>5 V Signalling</b>	<b>Units</b>
$V_{th}$	2.4	V
$V_{tl}$	0.4	V
$V_{test}$	1.5	V
$V_{max}$	2	0V
Input signal edge rate	1 V / ns	

$V_{max}$  specifies the maximum peak-to-peak waveform allowed for testing input timing.

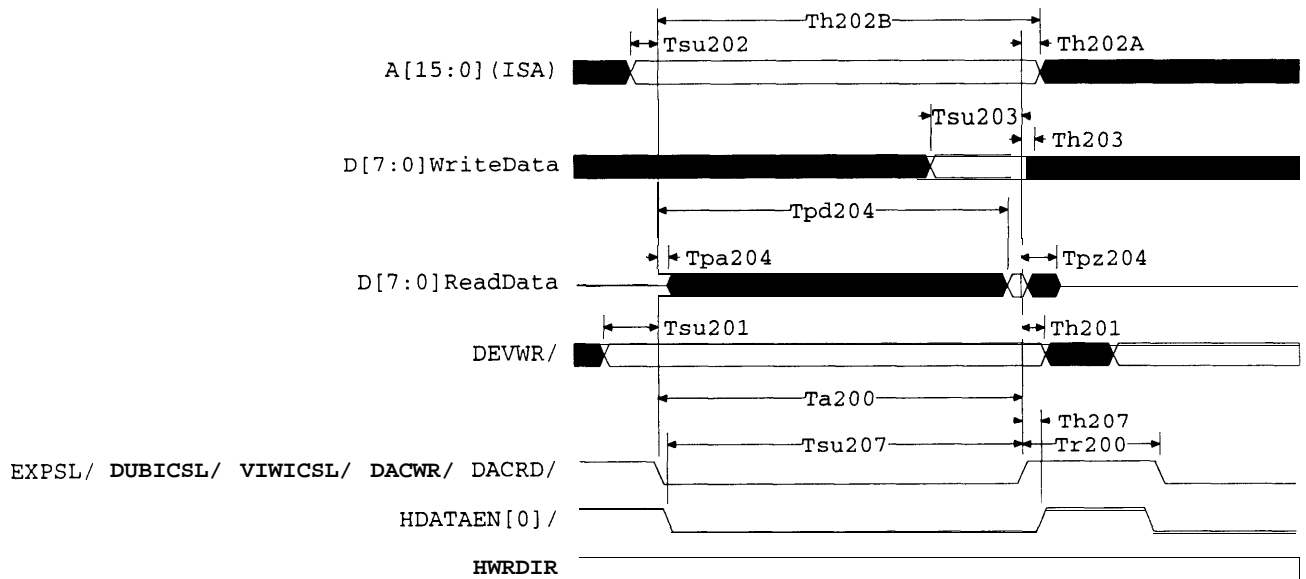

<i>Symbol</i>	<i>Parameter</i>	<i>Min</i>	<i>Max</i>	<i>Units</i>	<i>Notes</i>
$t_{val}$	CLK to Signal valid delay (bussed signals)	2	11	ns	(3) (2)
$t_{on}$	Float to Active delay	2		ns	(3)
$t_{off}$	Active to Float delay		28	ns	(3)
$t_{su}$	Input Setup time to CLK (bussed signals)	7		ns	(1)
$t_h$	Input Hold time from CLK	0		ns	(1)

**Table A-12: Host PCI 5 V Timing Parameters**

- (1) Refer to Figure A-2.
- (2) Minimum times measured with 0 pF equivalent load. Maximum times measured with 50 pF equivalent load. Actual test capacitance may vary. Correlate results to these specifications.
- (3) Refer to Figure A-3.

Notes:

- (1) Write cycle.
- (2) Read cycle.
- (3) Choose the lesser of the two values listed.

### A.2.3.3 Power Graphic Mode VRAM Interface Timing

The MGA Power Graphic Mode VRAM interface timing diagrams and parameter lists are found on the pages which follow. This timing data is based on 80 ns VRAMs, with the MCTLWTST register programmed to C4001010h.

**Table A-21: Page ZI Cycle Parameter List**

#### A.2.3.4 VGA Mode VRAM Interface Timing

##### Notes:

- (1) In the tables which follow,  $t_s$ ,  $t_h$  and  $t_l$  are the period of VIDCLK, VIDCLK high pulse width, and VIDCLK low pulse width, respectively.
- (2)
  - A = Standard Modes (CPU Writes),  
High-resolution 256-Color Modes (CPU Writes during Blank) (4)
  - B = High-Resolution 256-Color Modes (CPU Writes) (4)
  - C = Low Frequency Sequence (Display Reads),  
High-resolution 256-Color Mode (CPU Reads during Blank) (4)
  - D = Low Frequency Sequence (Catch Up Display Reads)
  - E = Low Frequency Sequence (CPU Reads)
  - F = High Frequency Sequence (Display Reads)
  - G = High Frequency Sequence (Catch Up Display Reads)
  - H = High Frequency Sequence (CPU Reads)
  - I = High-resolution 256-Color Mode (CPU Reads during Video) (4)
  - J = High resolution 256-Color Mode (Display Reads) (4)
- (3) The 'VRAM' column represents the timing that the VRAM must respect in order to support Super VGA modes.
- (4) For 1024 x 768 x 16 NI at 65 MHz, the pixel clock is divided by two, so high-resolution 256-color mode cycles have twice the number of clocks.
- (5) The WTN signals are high for at least one full cycle prior to the one indicated.
- (6) The WTN signals are high for at least one full cycle after the one indicated.

### A.2.3.5 Video Interface Timing

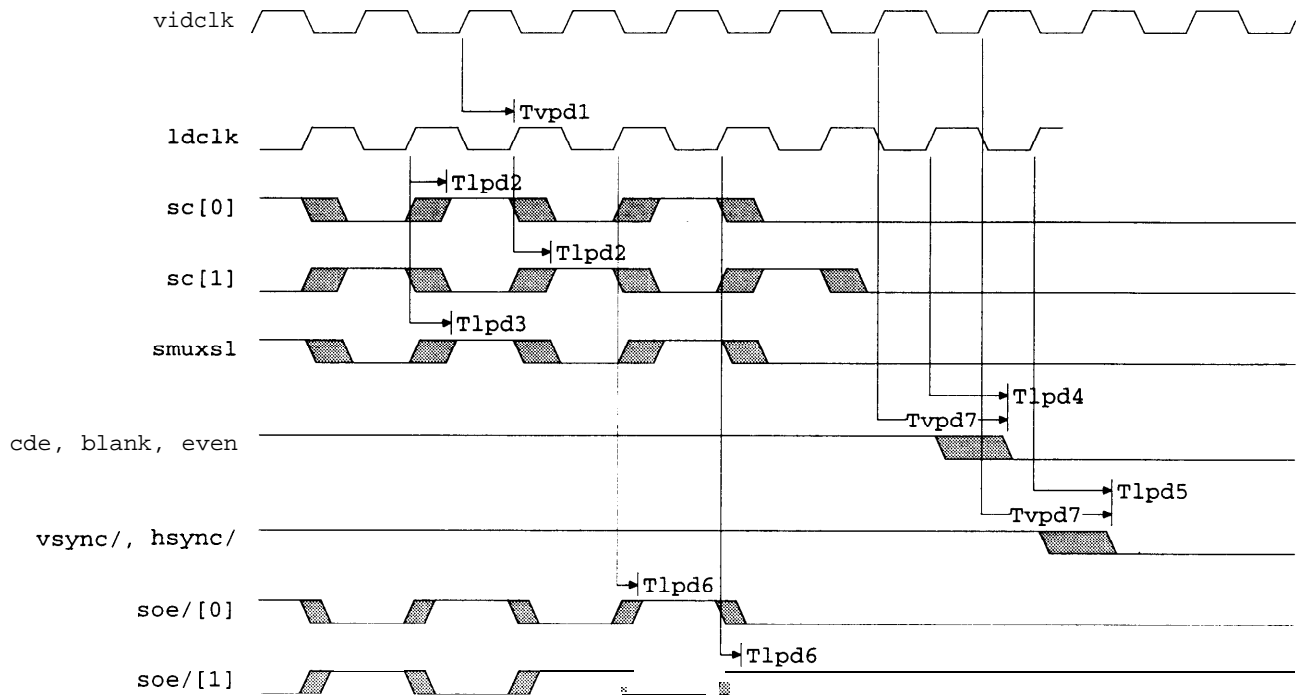

Figure A-19: Video Timing (No DUBIC Mode)

Figure A-20: Power Graphic Video Timing (DUBIC Mode)

**Figure A-21: VGA Mode (Normal) Video Timing**

**Figure A-22: VGA Mode (Slave) Video Timing**

❖ Note: In Figures A-21 and A-22, the signal names correspond to the No DUBIC mode signals. See Table A-25 for the No DUBIC mode signal names.

<i>Name</i>	<i>Min. (ns)</i>	<i>Max.</i>	<i>Comment</i>
Td1	6		vidclk HIGH
Td2	6		vidclk LOW
Td3a	15		vidclk cycle (VGA Normal)
Td3b	66		vidclk cycle (VGA Slave)
Tp3c	40		vidclk cycle (Power Graphic mode)
Td4a	2	58	vidclk → blank/, vsync/, hsync/ (VGA Slave) (No DUBIC mode) vidclk → vidinf<2:0> (VGA Slave) (DUBIC mode)
Td4b	2	30	vidclk → vidinf<3:0> (Power Graphic mode)
Td5	2	58	vidclk → vga<6:0>, va<11> (VGA Slave) (No DUBIC mode) vidclk → vga<3:0>, oe<4:2>/, va<11> (VGA Slave) (DUBIC mode)
Td6a	5		vidrst/ → vidclk (VGA Slave)
Td6b	5		vidrst/ → vidclk (Power Graphic mode)
Td7a	30		vidrst/ HOLD → vidclk (VGA Slave)
Td7b	20		vidrst/ HOLD → vidclk (Power Graphic mode)
Td8	6		ldclk HIGH (No DUBIC mode) vidinf<3> HIGH (DUBIC mode)
Td9	6		ldclk LOW (No DUBIC mode) vidinf<3> LOW (DUBIC mode)
Td10	15		ldclk cycle (VGA) (No DUBIC mode) vidinf<3> cycle (VGA) (DUBIC mode)
Td11	0.4	7	ldclk → vsync/, hsync/ (VGA) (No DUBIC mode) vidinf<3> → vidinf<1:0> (VGA) (DUBIC mode)
Td12	-4	1	ldclk → blank/ (VGA) (No DUBIC mode) vidinf<3> → vidinf<2> (VGA) (DUBIC mode)
Td13a	-4	2	ldclk → vga<5:0> (VGA) (No DUBIC mode) vidinf<3> → vga<3:0>, oe<4:3>/ (VGA) (DUBIC mode)
Td13b	-6	4	ldclk → vga<6>, va<11> (VGA) (No DUBIC mode) vidinf<3> → oe<2>/, va<11> (VGA) (DUBIC mode)
Tvpd1		10	vidclk → ldclk
Tlpd2	0	7	ldclk → sc<1:0>
Tlpd3	2	8	ldclk → smuxsl (1)
Tlpd4	1.5	7.5	ldclk → cde, blankN, even (1)
Tlpd5	1.5	7.5	ldclk → h[v]sync (1)
Tlpd6	0	4	ldclk ==> soeN<1:0>
Tvpd7	3	19	vidclk → h[v]sync, cde, blankN, even

**Table A-25: Video Interface Timing Parameter List**

(1) External resistance capacitor (RC) network must be added to respect most RAMDAC hold time constraints (3 ns).

Note:

SOEN<0> and SOEN<1> are both inactive for at least 1 ldclk cycle when switching between banks when NODUBIC = '01'.

### A.3 Mechanical Specification

# ATHENA PQFP 240-Pin (Plastic Quad Flat Pack) Square/Gull Wing

**LEGEND:** Maximum Inches (millimeters)  
Minimum Inches (millimeters)

**Figure A-23: ATHENA Mechanical Drawing**

### Detail A

### Detail B

**LEGEND:** Maximum Inches (millimeters)  
Minimum Inches (millimeters)

### Notes:

1. Co-planarity of all leads shall be within 0.1 mm (0.004 in.). This is the difference between the highest and lowest lead with seating plane -C- as reference,
2. Lead pitch determined at datum -D-.

**Figure A-24: ATHENA Mechanical Drawing (Details)**

## ***Appendix B: Customer Support***

***T***his appendix provides instructions on how to contact Matrox Customer support.

## B.1 Customer Support

- If you have a problem or question that isn't explained in this manual, you can contact the Customer Support Group at Matrox. Our phone numbers are:

- Outside the U.S. and Canada: (514) **685-2630**
- FAX: (514) **685-2853**

- You may address your technical support questions via electronic mail by posting a message to:

*GRAPH\_TS@MATROX.COM*

- You may also write to us at the following address:

Matrox Graphics Inc.  
Customer Support  
1055 St. Regis Blvd.  
Dorval, Quebec  
Canada H9P 2T4

## A

AC specifications ..... A-16

access

- ATHENA to RAMDAC ..... 6-6, 6-9
- restrictions (ISA configuration) ..... 6-7
- type ..... 5-10

address

- memory ..... 5-2

address generator

- data ..... 5-45
- state ..... 5-46

address processing unit ..... 2-2, 2-4

Address register ..... 5-26 - 5-29

Address register (VGA) ..... 5-82, 5-89, 5-94

ADGEN register ..... 5-45

alpha

- dithering and shading enable ..... 5-12
- mode select (EGA only) ..... 5-93

alternate palette ..... 5-101

analog monitor disable ..... 5-105

anti-aliasing

- background color select ..... 5-13
- foreground color select ..... 5-13

APU read/write command conversion ..... 2-4

AR0 register ..... 5-26

AR1 register ..... 5-27

AR2 register ..... 5-27

AR3 register ..... 5-28

AR4 register ..... 5-28

AR5 register ..... 5-29

AR6 register ..... 5-29

ATHENA

- design features ..... 6-2
- identification ..... 5-51
- sections ..... 2-2
- slaving ..... 6-25
- supported memory combinations ..... 2-4
- VGA functions ..... 2-2

ATHENA reset (VGA enabled) ..... 5-119

ATHENA to RAMDAC access ..... 6-6, 6-9

ATLAS

- register 'Category' ..... 4-6
- register mapping ..... 4-6

attributes

- address/data select ..... 5-76
- controller register index ..... 5-82
- drawing ..... 3-12

- register ..... 5-2

Attributes Address register ..... 5-77

Attributes Address/Data Select register ..... 5-76

automatic

- line wrap ..... 5-61
- wait mechanism ..... 5-58

auxiliary

- clock status ..... 5-115
- dip switch ..... 5-113
- window disable ..... 5-116

Auxiliary Index register ..... 5-104 - 5-105

Auxiliary Input Register 1 register ..... 5-113

Auxiliary Input Register 2 register ..... 5-114

auxiliary register index field ..... 5-105

## B

background

- color ..... 5-20
- Z value ..... 5-20

band width (EGA only) ..... 5-90

BCOL register ..... 5-20

BFIFO ..... 5-46

BGR format ..... 5-13

BIOS enable ..... 5-54

Bit Mask register ..... 5-99

BITBLT

- source ..... 5-11

blank

- horizontal ..... 5-64
- vertical ..... 5-66 - 5-67, 5-73

blink/intensity select ..... 5-83

blit mode selection ..... 5-12

block mode ..... 5-11

Boolean operation ..... 5-11

boot

- Power Graphic mode ..... 3-27
- VGA mode ..... 3-26

bus

- interface ..... 2-2
- sizing ..... 6-6

Bus FIFO

- count ..... 5-46
- empty flag ..... 5-46
- error interrupt clear ..... 5-48
- error interrupt enable ..... 5-48
- error interrupt status ..... 5-47
- full flag ..... 5-46

BUSCLK clock select ..... 5-106
